⑦ Continuous infusions are attractive for patients with unstable fluid balance or glucose homeostasis. The intermittent or cyclic infusion of PN over less than 24 hours, usually for 12 to 18 hours each day, is useful for hospitalized patients with limited venous access in whom administration of multiple other medications requires interruption of the PN infusion.[64] Cyclic PN may also minimize the incidence or reverse the liver injury associated with continuous PN therapy. In addition, this delivery mode allows patients receiving PN at home the ability to resume a relatively normal lifestyle.[16,60,64] Various protocols suggest incremental increases to the maximum infusion rate for a desired period of time followed by a gradual taper to discontinue the solution.[64] However, metabolically stable adults and children older than 2 years receiving ILE-based PN regimens are likely candidates for abrupt initiation and discontinuation of their intermittent PN regimen.[5,64,65] Cyclic PN should be used with caution for those with severe glucose intolerance, diabetes mellitus, or unstable fluid balance.

EVALUATION OF THERAPEUTIC OUTCOMES

⑧ Thorough and consistent monitoring of patients who are receiving PN is necessary to ensure that the desired nutritional outcomes are achieved and to prevent the occurrence of adverse effects or complications. Routine evaluation should include the assessment of the patient's clinical condition with a focus on nutritional and metabolic effects of the PN regimen. Serial documentation of a patient's response to their PN regimen is a helpful guide for determining appropriate adjustments in fluid, electrolyte, and nutrient therapies.

Serum concentrations of electrolytes, hematologic indices, and biochemical markers for kidney and liver function, and nutrition status should be measured before PN initiation and periodically thereafter depending on the patient's age, nutrition status, and clinical condition. The frequency of blood laboratory measurements for neonates and infants tends to be more conservative because of their smaller blood volumes and, in some cases, lack of central vascular access. Other important clinical measurements include vital signs, weight, total fluid intake and output, and nutritional intakes. Weekly measurements of height, length, and head circumference are helpful for monitoring nutritional changes in neonates. Monitoring parameters considered important for patients receiving PN and the suggested frequency of measurement for each are outlined in Fig. 165-3. Appropriate assessment and evaluation of patient data can identify potential complications that may be avoided or treated early. Monitoring protocols should be developed and tailored for the patient population, medical practices, and resources of individual practice settings.

COMPOUNDING, STORAGE, AND INFECTION CONTROL

The USP Chapter 797 details the procedures and requirements for compounding sterile preparations, including PN admixtures.[66] These standards apply to all healthcare settings in which sterile preparations are compounded and are used by boards of pharmacy, the FDA, and accreditation organizations such as The Joint Commission. Compounded sterile preparations are defined by risk level (immediate use, low, low with 12-hour beyond-use date, medium, and high) based on the probability of microbial, chemical, or physical contamination. PN solutions are classified as a medium-risk compounded sterile preparation. In general, PN solutions should be prepared using aseptic technique in a device or room that meets International Organization for Standardization (ISO) class 5 standards that is located in an ISO class 7 buffer area with an ISO class 8 ante area.[66] Preparation of PN formulations should be supervised by a pharmacist experienced in compounding IV solutions and knowledgeable about the stability, compatibility, and storage of PN admixtures. Quality assurance procedures should be developed to maintain safe and accurate admixture preparation. A standardized process for PN ordering, labeling, determining nutrient requirements, screening of the PN order, PN administration, and monitoring has been recommended to minimize risk of potentially life-threatening compounding errors.[5,62] The potential risk of infectious complications associated with PN solution contamination can be decreased greatly when pharmacy-based admixture programs follow specific guidelines developed to ensure proper compounding of PN solutions.[5,66] USP Chapter 797 is under revision.[67] However, the published version of the chapter, which became official on June 1, 2008, is enforceable.

In general, the type of solution being prepared dictates the compounding, storage, and infusion methods. The two most commonly used types of PN solutions are two-in-one admixtures with or without ILE co-infused into the PN administration line and TNAs. Methods for compounding PN admixtures vary based on a healthcare system's patient population and medical practices and the number of PN admixtures that need to be prepared. PN base admixtures may be prepared by using gravity-driven transfer of CAA stock solutions to partially filled bags of concentrated dextrose stock solutions.[5,68] Other practice settings may use standardized commercial PN products with CAA and dextrose, and ILE separated within a single bag that must be mixed before use.[5,44,62] Advances in compounding technology have facilitated the use of ACDs for preparing PN solutions. ACD systems usually include computer software that communicates calculated volumes of nutrient stock solutions directly to a transfer pump device that delivers fluid from the source container to the final container by either a volumetric or gravimetric fluid pumping system.[5,68] Advantages of ACDs include reduced personnel time and compounding materials and improved compounding accuracy. Disadvantages include the potential for equipment failure. Because of their acidic pH and hypertonicity, two-in-one PN admixtures are poor media for microbial growth.[5,40] However, several characteristics of ILE, such as isoosmotic tonicity, near neutral to alkaline pH, glycerol content, and preservative-free formulations favor microbial growth, particularly at room temperature.[35,41,56] Other factors contributing to the potential for compromised ILE stability or sterility include the container material, length of ILE co-infusion with PN, length of time between administration set change, effect of infusion from the source container such as the original container, and infusion of ILE transferred to a secondary container. When ILEs are added to dextrose-CAA solutions to make TNAs, the growth potential is decreased, presumably because of the protective effects of the hypertonic dextrose-CAA solution and decreased pH.[35,41,56]

Because of the risk for microbial contamination, manufacturers recommend storage of PN solutions for as little time as possible after preparation. The USP 797 standards recommend storage times of not more than 30 hours at controlled room temperature (20°C-25°C [68°F-77°F]) and not more than 9 days at refrigerated temperatures (2°C-8°C [36°F-46°F]) for all medium-risk compounded sterile preparations, including PN admixtures.[66]

When co-infusing ILE with PN (ie, not as a TNA), the appropriate ILE dosage form (original packaging or re-packaged doses) and administration time to minimize risk of contamination is controversial. Unfortunately, the Centers for Disease Control and Prevention (CDC) guidelines offer no guidance for administration times.[58] Instead, the guidelines recommend administration tubing replacement every 24 hours for both ILE infused separately or when given as part of a TNA. The guidelines also recommend administration tubing replacement no more frequently than at 96-hour intervals but at least every 7 days for tubing used continuously for infusion of IV solutions other than blood, blood products, or ILE. More conservative recommendations have been presented.[5,56] The ASPEN 2013 PN Safety Consensus suggests a 24-hour infusion time and administration tubing replacement every 24 hours for TNAs and two-in-one PN formulations and a 12-hour infusion time and administration tubing replacement every 12 hours for ILE co-infused separately.[5]

Compliance with ASPEN recommendations in pediatric patients is problematic. For example, an infant receiving 3 g/kg/day ILE at the recommended infusion rate of 0.15 g/kg/hr to promote lipid clearance and minimize metabolic complications, would require at least a 20-hour infusion.[16,69] To accommodate prolonged ILE infusions, many institutions routinely infuse ILE separately over 24 hours and change administration tubing for the ILE and PN solution with each new bag because the use of TNA formulations is not recommended in neonates and infants. In addition, since commercially available ILE products are not manufactured in unit volumes suitable for safe use in neonates and infants, institutions commonly transfer ILE from the original container into another container to accommodate the smaller patient-specific volume to decrease risk of adverse events from infusion-related errors. A variety of methods have been utilized for repackaging ILE. Syringe repackaging and aseptic transfer into sterile bags with the use of an ACD are not recommended because of higher contamination rates. Other methodologies, such as aseptic withdrawal of an appropriate ILE volume resulting in a patient-specific dose in the original manufacturer's container (drawing-down) has been recommended as a potential option.[41,56,69] These multifactorial concerns with providing ILE to pediatric patients have been addressed by the ASPEN Safety Consensus Recommendations.[5] When prolonged ILE infusions are required in neonates and infants, the daily dose should be divided in two separate 12-hour infusions. The ILE container and administration tubing should be replaced every 12 hours.[5] When utilizing repackaged ILE, the infusion time should not exceed 12 hr/Unit and the administration tubing should be changed with each new infusion.[5,41,56,69]

Stability and Compatibility

Comprehensive current information regarding compatibility and stability of PN solutions can be found in several reference sources such as *ASHP Injectable Drug Information*[70] and *King Guide to Parenteral Admixtures*.[71] In many cases, the answer to a compatibility question may not be readily available, and a review of the primary literature may be necessary. When information is not available, clinical judgment and experience must be used to resolve the situation.

The stability of a PN formulation is determined by the rate or degree of component degradation and any resulting changes in chemical integrity or pharmacologic activity that may render the formulation unsuitable for safe administration.[22] In general, the sterile combination of PN components accelerates the rate of physicochemical destabilization of all of the components in the formulation; certain amino acids, vitamins, and ILE are the most susceptible nutrients.[5,22,28,46] When compounded and stored appropriately, the degree of degradation is usually not clinically relevant for most patients receiving short-term PN because many patients have sufficient stores of those susceptible nutrients to support any short-term periods of suboptimal intake. However, nutrient degradation that is more extensive may be problematic for patients with marginal nutrient stores who receive long-term PN. TNAs present additional stability challenges because of the presence of ILE in the solution. ILE stability in TNAs is affected by the amino acid and dextrose concentration, solution pH, order of mixing, electrolyte amounts, and final TNA volume as well as container material, storage conditions, and addition of non-nutrient medications. Information on the effect of specific electrolyte concentrations on TNA stability is limited. In general, ILE stability is affected by the PN cation content. Divalent and trivalent cation additives such as calcium and magnesium have a greater destabilizing potential compared with monovalent cation additives such as sodium and potassium. However, when given in sufficiently high concentrations, monovalent cation additives may also increase instability. Cations act to reduce the surface potential of the emulsion droplet, thereby enhancing tendency to aggregate and ultimately, in some cases, destabilize the solution to coalescence or a “cracked” admixture.[5,22,40] When a cracked ILE occurs, the oil phase separates from the water phase, resulting in the appearance of free oil fat globules. Early stages may appear as subtle changes in the uniformly white appearance of the TNA, which may progress to yellow oil streaks throughout the bag or development of an amber oil layer at the top of the admixture bag. TNA formulations with any visible free oil should be considered unsafe for parenteral administration because infusion of circulating fat globules may be of sufficient size to accumulate in the pulmonary vasculature and potentially compromise respiratory function. In general, the likelihood of preparing an unstable TNA formulation can be minimized by maintaining the final concentrations of CAA greater than 4%, dextrose greater than 10%, and ILE greater than 2%.[5] Specific guidelines for compounding TNAs are reviewed elsewhere.[2,5,31–35,56]

Because of differences in pH among various CAA products and phospholipid content among ILE products, the manufacturer of each product should be consulted for compatibility and stability information before routinely admixing components. One approach to compounding TNAs manually is to combine CAA, dextrose, and sterile water (if necessary) followed by the addition of electrolytes, vitamins, and trace elements. Then the solution should be visually inspected for precipitate or other particulates. Finally, ILE may be added and the solution should then be visually inspected again to ensure a uniform emulsion exists.[31–34] Mixing components in this specific order may not be possible with the use of ACDs. Although CAA, dextrose, and ILE may be simultaneously transferred to an admixture container, the ACDs manufacturer should be consulted for the optimal mixing sequence to ensure safe compounding of TNA formulations.

The precipitation of calcium and phosphorus is a common interaction that is potentially life-threatening.[16,22,72] The risk of precipitate formation is greater with increased solution temperature and pH, higher concentrations of calcium and phosphorus, lower concentrations of amino acids and dextrose, use of the chloride salt of calcium, improper mixing sequence when adding calcium and phosphorus salts, and the presence of other additives (including ILEs).[16,22,72] In general, steps to minimize risk of calcium and phosphate precipitation in PN admixtures include the use of calcium gluconate instead of calcium chloride because it is less reactive, adding phosphate salts early in the mixing sequence, adding calcium last or nearly last, and agitating the mixture throughout the admixture process to achieve homogeneity. PN admixtures with a lower final pH should be used when clinically appropriate. Higher final concentrations of dextrose and CAA and lower final concentrations of ILE favor a lower admixture pH. CAA product-specific solubility curves that are available from the manufacturer or primary literature should be consulted to project calcium and phosphorous solubility. The calculation of a sum or product of calcium and phosphate concentrations should not be used as the sole criterion for determining solubility because the product of calcium and phosphate concentrations vary inconsistently as calcium concentration decreases and phosphate concentration increases.[72]

Electrolyte stability in TNA solutions is difficult to assess because of poor visualization of a precipitate if one occurs. PN solutions for neonates and infants tend to contain larger amounts of calcium and phosphorus, as well as other divalent cations, that limit the use of TNAs. Because of the limited amount of published stability information, the use of a two-in-one admixture with separate administration of ILEs is recommended for neonates and infants.[56] In general, alternative methods of delivering electrolytes or medications should be pursued in any clinical situation in which TNA compatibility information is lacking. Because the addition of bicarbonate to acidic PN admixtures may result in the formation of carbon dioxide gas and insoluble calcium and magnesium carbonates, sodium bicarbonate use in PN admixtures is not recommended. Use of a bicarbonate precursor salt such as acetate usually is preferred.[22]

Vitamins may be affected adversely by changes in solution pH, presence of other additives, storage time, solution temperature, and exposure to light.[22,28] Because of variable stabilities of individual vitamins, IV vitamin solutions should be added to the PN solution as near to the time of administration as is clinically feasible and should not be in the PN solution longer than 24 hours.

Peroxide concentrations are increased in ILE and dextrose-amino acid solutions after addition of injectable multivitamins or exposure to air or light.[73] Peroxides and associated metabolites have negative effects on organ and immune function. Specifically, peroxides are associated with neonatal hypoxic-ischemic encephalopathy, intraventricular hemorrhage, periventricular leukomalacia, chronic lung disease, retinopathy of prematurity, and necrotizing enterocolitis.[73] Neonates and infants are at increased risk for harmful effects of peroxides because they receive a higher daily peroxide load from PN solutions compared to adults and they have lower endogenous antioxidant levels. However, premature infants are more vulnerable to consequences of peroxide formation in PN admixtures.[73] Complete PN photoprotection from light (admixture and administration line) beginning as soon as possible during the PN compounding process and continued until the entire PN admixture and ILE infusion is complete is recommended to minimize risk of peroxides formation and by-products of lipid peroxidation.[73]

Many patients receiving PN also receive other IV medications. The compatibility of these medications with the PN solution is an important consideration for safe and effective medication delivery. Although some medications may be added directly to the PN solution and administered at the same rate as the PN infusion, most are administered as a separate admixture co-infused in the PN line. Several criteria should be considered before medications are added directly to the PN solution because of the potential for ineffective medication therapy or other complications associated with physiochemical incompatibility and stability of the PN solution.[22,56] First, the medication should be stable for at least 24 hours and should have pharmacokinetic properties appropriate for continuous infusion. Second, the chemical and physical compatibility of the medication with PN admixture components and other medications that may be co-infused concomitantly into the PN line should be verified. Advantages of using PN admixtures as medication vehicles include consolidation of dosage units, improved pharmacodynamics for certain medications, conservation of fluid in volume-restricted patients, fewer venous catheter violations, and decreased compounding and administration times. However, a major disadvantage to the use of PN solutions as medication-delivery vehicles is the lack of compatibility and stability data. Medications frequently added to PN solutions include regular insulin and histamine-2 receptor antagonists.[22,56]

COMPLICATIONS OF PARENTERAL NUTRITION

Mechanical and Technical Complications

Mechanical and technical complications include malfunctions in the system used for IV delivery of the solution, such as infusion pump failure, problems with administration sets or tubing, or the CVC. Although problems associated with infusion pumps and administration sets can be decreased by appropriate equipment selection and routine care and monitoring, CVC-related complications are potentially life-threatening. Pneumothorax, catheter misdirection or migration into the wrong vein or improper positioning within the cardiac chambers, arterial puncture, bleeding, and hematoma formation may occur during surgical placement of the catheter. Many of these complications, in addition to venous thrombosis and air embolism, can occur after insertion. CVCs occasionally occlude or break during use and if these problems cannot be rectified easily, the catheter may need to be surgically replaced.

Infectious Complications

Infectious complications can be a major hazard for patients receiving CPN because of the increased risk associated with the presence of an indwelling CVC. The source of a CVC infection may be skin organisms from the catheter insertion site, contamination of the catheter hub, or hematogenous seeding of the catheter from a distant site. In addition, patients receiving PN therapy are often predisposed to infection because of compromised immunity or concomitant infection. Frequent use of broad-spectrum antibiotic therapy and malnutrition are also predisposing factors for development of infection. The risk of catheter infection is increased for those who require multiple manipulations of the line used for PN administration as well as those who experience, poor catheter placement technique, and poor CVC and insertion site care.[58]

Infection rarely develops secondary to solution contamination.[58,63] Strict adherence to protocols for preparation of PN admixtures should minimize this occurrence.[66,74] Catheter-related bloodstream infections (CRBSIs), defined as the presence of clinical manifestations of infection (eg, fever, chills, hypotension) associated with bacteremia or fungemia resulting from no apparent source other than the catheter, are common sources of systemic infection.[74] Before this diagnosis can be made, there should be evidence of more than one positive blood culture result obtained from the peripheral vein with growth of the same organism from a blood culture obtained from the catheter or catheter segment. When a CRBSI is suspected or confirmed, appropriate antimicrobial therapy should be initiated. Retention or removal of the CVC depends on the patient's severity of illness, the suspected or identified pathogen, and the type of catheter involved. The catheter may be removed and replaced in the same site, the catheter may be removed and replaced at a different anatomic location, or it may not be replaced.[74] Filling the catheter with antimicrobials such as vancomycin or antiseptics such as 70% alcohol and allowing the solution to dwell for a period of time while the catheter is not in use is referred to as a catheter lock.[58] Antimicrobial catheter locks have been used to prevent and treat CRBSI in patients with long-term catheters such as those receiving home PN.[58,59]

Metabolic and Nutritional Complications

⑨ Metabolic and nutritional complications associated with PN therapy are numerous, frequently multifactorial in origin, and potentially fatal if left untreated. Metabolic abnormalities related to substrate intolerance, fluid and electrolyte disorders, and acid-base disorders are summarized in multiple recent review articles and their management is briefly summarized in the following sections.[28–30,39,55,75–82]

Liver Disease

PNALD presents as elevations in total bilirubin, aspartate aminotransferase, alanine aminotransferase, and alkaline phosphatase. Both adult and pediatric patients who receive PN are at risk for developing PNALD; it occurs in approximately 50% to 60% of children who receive long-term PN, with a higher incidence in premature infants.[28,29,75] No single etiology has been identified, although several risk factors have been described, such as, degree of prematurity, sepsis, hypoxia, lack of EN, small bowel bacterial overgrowth, GI conditions requiring surgical intervention, duration of PN therapy, and long-term administration of excessive calories.[29,39,75] PNALD in infants is characterized clinically by a serum direct bilirubin concentration greater than 2 mg/dL (more than 34.2 μmol/L).[29] Taurine deficiency has been proposed as an etiology of cholestasis for preterm infants and neonates.[29,39] Taurine is a conditionally essential amino acid that is not present in standard CAA solutions but is important for neonatal and infant bile metabolism. However, the preventative or therapeutic benefit of PN regimens with CAA solutions containing supplemental taurine is unclear. SO-based ILEs contain large concentrations of plant sterols or phytosterols, which are inefficiently metabolized to bile acids by the liver and may impair bile flow. Improvement or reversal of PNALD may occur for patients who receive FO-ILE.[37,39] Other PNALD treatments that have been investigated include providing reduced doses of SO-based ILE and use of enteral fish oil in patients with limited oral intake.[39,76]

Risk factors for PNALD in adults include preexisting liver disease, sepsis, preexisting malnutrition, extensive bowel resection, prolonged duration of PN therapy, lack of enteral intake, nutrient deficiencies such as choline deficiency, and long-term administration of excessive calories.[28,29,39,75] PNALD in adults typically presents as steatosis and steatohepatitis on biopsy. Clinically, PNALD is characterized by mild elevations in serum liver enzymes, usually less than three times the upper limit of normal, with peak enzyme levels usually occurring between 1 and 4 weeks after initiating PN. In many cases, the liver abnormalities improve or resolve with manipulation of substrate intake or discontinuation of PN therapy. However, in severe cases, liver dysfunction may progress to overt failure and death despite use of traditional therapies such as using cyclic PN, ursodiol, and oral antibiotics for bacterial overgrowth; maximizing enteral feeding; and avoiding sepsis and parenteral overfeeding.[28,29,75] Intestinal transplant with or without liver transplantation has become a treatment option for PN-dependent patients who have progressive PNALD.

Hypertriglyceridemia

Hypertriglyceridemia, defined as serum triglyceride concentrations greater than 400 mg/dL (4.52 mmol/L) for adults and 150 mg/dL (1.70 mmol/L) to 200 mg/dL (2.26 mmol/L) for preterm infants, neonates, and older pediatric patients, may occur in patients receiving ILE-based PN. Risk factors include preexisting liver or pancreatic dysfunction, sepsis, multiple-organ failure, degree of prematurity, ILE infusion rate, and dose.

ILE-associated hypertriglyceridemia is generally caused by defective lipid clearance or an excessive rate of ILE administration.[28] Premature infants and neonates have relatively slower lipid clearance than do adults because of immature metabolic pathways, including decreased lipoprotein lipase activity.[16,41] Reducing the ILE infusion rate or dose or withholding ILE therapy should be considered when patients present with hypertriglyceridemia or lipemic serum.[28] Use of low-dose heparin (1 unit/mL of two-in-one PN formulation) to stimulate lipoprotein lipase activity may be a potential therapeutic intervention to treat ILE-associated hypertriglyceridemia in neonates.[16] However, the risk associated with heparin delivery via PN may outweigh the clinical benefits because of the potential for compounding errors associated with confusion between heparin and insulin doses.[77] Carnitine does not have a defined role for treatment of ILE-associated hypertriglyceridemia.[16,28]

Hyperglycemia

Hyperglycemia is one of the most common complications of PN administration and is associated with a history of diabetes mellitus, metabolic stress, adverse medications reactions to agents such as glucocorticoids, and excessive carbohydrate administration. In the pediatric population, additional risks for hyperglycemia include prematurity and surgery. The optimal blood glucose concentration for acutely ill hospitalized patients receiving PN is not known. However, a target range of 140 to 180 mg/dL (7.8-10 mmol/L) has been suggested for adults, and less than 150 mg/dL (8.3 mmol/L) has been suggested for neonates.[78,79] Clinical management of PN patients with hyperglycemia has not been well studied and is largely empiric.[80,81] Blood glucose concentrations can be controlled with regular insulin, which may be given subcutaneously or added to the PN formulation. One approach for adult PN patients requiring insulin or oral hypoglycemic agents before starting PN therapy is to initiate PN with approximately 100 to 200 g of dextrose and add 0.05 to 0.1 Units of regular insulin per gram of dextrose in the PN solution for those patients with mild hyperglycemia (140-180 mg/dL [7.8-10 mmol/L]). The insulin dose may be increased to 0.15 to 0.2 Units/g of dextrose for patients with moderate hyperglycemia (181-200 mg/dL [10-11.1 mmol/L]).[28,80,81] Others have suggested continuing preadmission basal insulin with long-acting insulin (detemir or glargine). Response to blood glucose monitoring prior to initiating PN therapy can be useful in determining initial insulin dosing. Blood glucose concentrations should be monitored every 4 to 6 hours. Blood glucose measurements above the goal range should be treated with short-acting insulin administered subcutaneously according to an appropriate sliding scale (see Chapter 94). The insulin dose is modified daily by adding 60% to 100% of the sliding-scale insulin given over the previous 24 hours to the PN formulation daily until blood glucose concentrations are stable and within the target range. When blood glucose measurements are stable, the dextrose dose may be advanced to achieve the therapeutic goal and the frequency of monitoring blood glucose concentrations may be decreased after blood glucose concentrations are stable within the target range at the goal dextrose dose. Use of a separate IV insulin infusion is most commonly used for pediatric patients, but it may also provide better and safer glycemic control for patients with large insulin requirements or those with unstable marked fluctuations in their blood glucose concentrations.

Refeeding Syndrome

Severe and rapid declines in serum phosphate, potassium, and magnesium concentrations; fluid retention; and other micronutrient deficiencies are common features of the refeeding syndrome.[82] Individuals at greatest risk for refeeding syndrome are severely malnourished patients with considerable weight loss who receive aggressive nutritional supplementation. In addition, those who are unfed for 7 to 10 days with evidence of stress or nutritional depletion; those with chronic diseases causing undernutrition such as cancer, cardiac cachexia, chronic obstructive pulmonary disease, or cirrhosis; and individuals who were previously morbidly obese and have experienced massive weight loss are at heightened risk for this syndrome.[82] Electrolyte abnormalities are related to acute provision of macronutrient substrates that promote anabolism in an environment of depleted total body stores of phosphorus, potassium, and magnesium. Recommendations for initiating PN in adults at risk for refeeding syndrome include providing 100 to 150 g of dextrose or 10 to 20 kcal/kg (42-84 kJ/kg) for the first 24 hours and advancing calories by 33% of goal every 1 to 2 days. Recommendations for initiating PN in pediatric patients include providing a maximum of 40% to 50% goal, and initiating the glucose infusion rate at approximately 4 to 6 mg/kg/min. The dextrose dose should be advanced by 1 to 2 mg/kg/min daily to a maximum dose of 14 to 18 mg/kg/min depending on blood glucose response. Other non-PN sources such as IV fluids or EN should be considered as well. Supplemental thiamine 100 mg/day for adults and 2 mg/kg/day to a maximum of 100 to 200 mg/day for pediatric patients should be considered before feeding or before initiating dextrose-containing IV fluids in patients at risk.

Because the metabolic abnormalities described with refeeding syndrome are related primarily to acute provision of large amounts of dextrose, the goal protein dose may usually be provided with the initial PN infusion. Pediatric PN regimens are usually advanced over several days as a general practice for all pediatric patients.

Complications Associated with Long-Term Parenteral Nutrition

Other nutritional complications of PN therapy may develop over a prolonged course of therapy (weeks to months) as a result of inappropriate intake of a particular nutrient. Certain conditions, such as metabolic stress in a previously malnourished patient, may elicit symptoms of deficiency much earlier if a nutrient is not appropriately provided. For example, lactic acidosis and other life-threatening complications associated with severe thiamine deficiency may occur in patients who received PN solutions without multivitamin supplementation.[46] Maintenance doses of vitamins, trace elements, and essential fatty acids should be provided to all patients with normal age-related organ function receiving PN.

Essential Fatty Acid Deficiency

Patients receiving PN regimens without ILEs for weeks to months are at risk for development of EFAD. Clinical signs of EFAD include hair loss, desquamative dermatitis, thrombocytopenia, malabsorption, and diarrhea resulting from changes in intestinal mucosa.[28,36] EFAD may also be diagnosed by evaluating plasma fatty acid profiles. Although this assessment is not routinely available, it can be provided by several larger regional laboratories. Historically, a triene-to-tetraene ratio more than 0.4 was considered biochemical evidence for EFAD, however, individual laboratory reference ranges should be used when evaluating patients for EFAD.[16,36] Although the time in which EFAD may develop depends on the patient's nutrition status, disease state, and age, these manifestations may occur 2 to 4 weeks after initiation of lipid-free PN in adults and within 48 hours in newborn infants.[36,37]

Metabolic Bone Disease

Metabolic bone disease may occur in adults and children receiving long-term home PN.[28,29] This disorder in adults is characterized by osteomalacia with or without osteoporosis that may present without associated clinical, radiologic, or biochemical abnormalities. The diagnosis may not be made for premature infants until after the development of bone fractures or overt rickets. The etiology is poorly understood and likely multifactorial. Treatment options include pharmacologic intervention, calcium and vitamin D supplementation, and exercise. Because excessive vitamin D has also been implicated in the development of metabolic bone disease, others have recommended removal of vitamin D from the PN for patients with a normal 25-hydroxyvitamin D concentration and low serum parathyroid hormone and 1,25-hydroxyvitamin D concentrations.[28,29]

Trace Element and Vitamin Complications

Clinical symptoms of trace element deficiencies, although rare, may occur for patients receiving long-term PN. More commonly, decreased serum trace element concentrations are seen in a variety of patient populations. However, the clinical significance of abnormally low concentrations of many trace elements is unknown because serum concentrations often do not correlate with total body stores.[46] Occasionally, patients may develop clinical toxicities from elevated vitamin or trace element concentrations as the result of increased intake or decreased metabolism. These abnormalities are frequently associated with an underlying disease state such as severe kidney or hepatic failure and may necessitate reduction in vitamin and trace element intake.

Many trace elements are present in PN components as contaminants.[46,56] In patients with normal organ function who receive PN supplemented with commercially available parenteral multiple trace element solutions, elevated serum concentrations of trace elements such as chromium and manganese may develop.[46,56] Aluminum is a common contaminant of many sterile IV solutions, including those used for compounding PN. Calcium and phosphorus solutions are among those components with the highest levels of aluminum contamination.[83,84] Aluminum accumulation may occur during long-term PN therapy, especially for patients with reduced kidney function, and is associated with abnormal neurologic and hematologic function and metabolic bone disease in adults and premature infants.[28,83,84] Preterm infants are at higher risk of aluminum toxicities because they receive larger doses (µg/kg) from PN solutions than adults.[84] Preterm infants are also more likely to retain aluminum because of immature kidney function. Although the maximum safe level of IV aluminum intake is unknown, parenteral doses of 4 to 5 µg/kg/day may be associated with central nervous system and bone toxicity.[85] Even smaller amounts may result in tissue accumulation but no documented toxicity.

The FDA implemented a mandate in 2004 to restrict aluminum content in large-volume PN stock solutions (CAA, dextrose, sterile water for injection, ILE) to a maximum of 25 µg/L and for manufacturers to indicate the maximum aluminum concentration at expiration for both large- and small-volume parenteral products used for PN.[85] Actual aluminum concentrations in parenteral products to be lower than the amounts described on the manufacturer's label, however, aluminum amounts in PN solutions still exceed FDA guidelines.[83,84] In addition, the aluminum content of parenteral products varies considerably during the shelf life of the products and increases with time because of leaching from glass containers. The amount of aluminum contamination delivered to patients receiving long-term parenteral therapy such as chronic PN patients or dialysis patients, can be substantially reduced if newer stock solutions are used to prepare their PN.[83,84]

HOME PARENTERAL NUTRITION

Advances in technology for the delivery of IV solutions have allowed medically stable patients who require extended PN therapy to be maintained indefinitely on IV nutrition. An increasing concern for cost containment of healthcare services has fostered use of sophisticated infusion devices to provide PN at home. Numerous programs are now available outside the traditional healthcare setting to support patients who require long-term or permanent PN. Standards have been developed to promote safe and effective care.[60] Home PN services may be coordinated and administered through a hospital or by a commercial home care company.[59]

Many factors are considered in selecting candidates for home PN therapy. Meaningful benefit must be expected from the therapy. Examples of patients who have been maintained successfully with home PN include those with severe GI dysfunction secondary to Crohn's disease, ischemic bowel disease, severe GI motility disorders, extensive intestinal obstruction, and congenital bowel dysfunction.[59] The patient and the patient's caregiver must be willing to complete training and assume numerous responsibilities for managing the new daily routine. Other logistics such as funding, procurement of solutions and supplies, and clinical management and follow-up must be individualized for each patient in order to achieve the desired outcomes.[59]

Patients commonly receive PN solutions from their home care provider. IV vitamins or other additives may be added daily by the patient or caregiver, depending on the arrangement with the home care provider. The solution is administered through the night by infusion pump over 8 to 20 hours.[59,64] A cycled regimen allows the patient time away from the pump during daylight hours and provides many patients with the freedom to have a reasonably normal daily routine. Clinical management and follow up are performed periodically according to the needs of the patient and the protocol of the home care provider or the managing healthcare team. A coordinated effort among several healthcare professionals, including physicians, pharmacists, nurses, dietitians, social workers, and the patient and the patient's caregiver, as well as the suppliers, is paramount to providing safe and effective management. Home PN affords some patients the potential for an ambulatory lifestyle while maintaining an IV feeding regimen that was previously only available in the hospital setting. For others, home PN may contribute to a better quality of life in the comfort of their homes.[59]

PHARMACOECONOMIC CONSIDERATIONS

Determining the true cost of PN support is difficult because numerous variables affect the provision of PN and the clinical response to therapy. PN therapy cost variables include the underlying indication for treatment, the administration setting (home or acute care), timing of PN initiation, therapy associated complications, and the type of PN formulation provided (compounded or standardized commercial PN product).[59,86–91] Expenses associated with PN therapy may be categorized as direct and indirect costs.[89] Direct costs may be further categorized as fixed or variable costs. Fixed costs do not depend on the volume of patients receiving therapy. For example, an ACD and the tubing sets required to transfer volumes of stock solutions to the administration bag would be considered fixed costs in many practice settings. These costs per patient tend to be highest in low-volume environments. Variable costs such as PN administration bags or standard commercial PN products depend directly on the number of patients receiving PN. Other direct costs include ancillary services required by patients receiving PN and costs related to the management of PN associated complications.

Clinical benefits and other clinical effects of PN (ie, reduction in hospital length of stay and frequency of complications) in specific patient populations have been evaluated but few investigations include a comprehensive economic assessment of PN therapy. Attempting to measure the cost or cost savings associated with the benefits of PN therapy and other clinical effects is difficult.[87,88] Clinical outcome measurements and hence economic outcomes are influenced by multiple factors, including experimental design, sample size, and specific health system practices.[87,89–93] More recent cost analyses for PN therapy have focused on timing of initiating therapy in critically ill patients and choice of PN formulation (compounded or standard commercial PN product). The cost advantage of supplemental PN in critically ill patients unable to meet nutritional goals within 24 to 48 hours of intensive care unit (ICU) admission is unclear.[91] Similarly, the cost advantage of using standard commercial PN products compared to PNs compounded with an ACD is uncertain.[93,94]

Although the results of economic analyses of PN remain controversial, similarities among several reports provide a basis for minimizing the costs of PN therapy:

1. Use PN only for the most appropriate patients as described by institution-specific criteria based on current consensus statements. EN should be used whenever feasible because the associated costs and complications are demonstrated to be less than those associated with PN.[90,92,95]

2. Reassess the need for routine laboratory monitoring measurements used for PN therapy. In general, the level of laboratory monitoring should decrease as a patient's clinical condition stabilizes.

3. Minimize the direct cost of PN by using efficient purchasing practices for PN solutions and compounding supplies through contract purchasing, streamlined compounding procedures, standardized administration times, single-bag PN solutions, and optimized monitoring plans. Some institutions may realize direct cost savings with use of standardized, commercial PN products depending on the usual daily PN census and patient population.[94,96] Others may reduce direct costs by outsourcing PN compounding to a third-party compounding pharmacy facility.

PHARMACOTHERAPY CONSIDERATIONS

⑩⑪ Considerations for individualizing a patient's PN regimen include goals determination based on a patient-specific nutrition assessment, selection of the optimal type of available vascular access, and macronutrient and micronutrient requirements. In general, both macronutrient and micronutrient doses are age and weights based but are also affected by the patient's degree of metabolic demand, organ function, other medication therapy, exogenous losses, and acid-base status. Nutrient amounts provided by the PN may also require adjustment based on enteral intake either orally or by feeding tube in patients with recovering GI tract function.

Patient-specific caloric goals include (a) adequate energy intake to promote normal growth and development in neonates, infants, and children; (b) energy equilibrium and preservation of fat calorie stores in well-nourished adults; and (c) positive energy balance in malnourished patients with depleted endogenous fat stores. Overweight patients with a BMI above 30 kg/m^2 may require less caloric support than nonobese patients with the same clinical condition.[12] Critically ill adults may also benefit from a hypocaloric regimen.[12] Specific nitrogen goals are positive nitrogen balance or nitrogen equilibrium and improvement in the serum concentration of visceral protein markers such as transferrin or prealbumin in patients without systemic inflammation. Routine monitoring is necessary to ensure that the nutrition regimen is suitable for a given patient as the patient's clinical condition changes and to minimize or treat complications. The PN component doses usually require individualized adjustments as the patient's clinical condition affects further changes in metabolic stress, organ function, fluid and electrolyte balance, and acid-base status.

Appropriate patient selection, assessment, and monitoring are key to successful PN therapy and the prevention of unnecessary complications. Because pharmacists are actively involved in the provision of PN at many levels, including order verification, PN compounding and dispensing, direct patient care, education, and research, nutrition support is recognized as a pharmacy practice specialty.[97] In addition, as the interprofessional team based approach to specialized nutrition support has evolved, standards of practice have been defined for pharmacists as well as for other healthcare professionals.[4,8–10] Standardized order forms and monitoring protocols are useful tools to ensure safe administration and monitoring of PN therapy. The future of PN therapy and the role of nutrition-support clinicians will be affected primarily by new insights from clinical research and economic challenges in the evolving healthcare environment.

SELF-ASSESSMENT QUESTIONS

Questions 1 through 8 refer to the following patient case:

A 65-year-old woman was admitted to the hospital after a 3-week history of nausea, vomiting, diarrhea, and increasing abdominal girth. The initial physical examination revealed a pelvic mass, which was confirmed by a computed tomography (CT) scan. A barium enema revealed an obstruction of the sigmoid colon. The patient was subsequently taken to surgery for exploratory laparotomy at which time the patient underwent an omentectomy, a jejunal-ileal anastomosis, and CVC placement. After surgery, the patient developed hypotension and respiratory failure requiring mechanical ventilation. The patient continued to have a distended abdomen on postoperative day 9. A nasogastric tube was placed for low continuous intermittent gastric suction with approximately 600 to 800 mL/day output. The patient has no kidney or liver function laboratory abnormalities and remains hemodynamically stable requiring continuous IV norepinephrine for blood pressure support. She is receiving propofol 25 mL/hr IV for sedation. The Nutrition Support Team is consulted to begin PN. The patient's goal regimen was determined to be (final concentrations) 6% amino acids and 20% dextrose at 75 mL/hr continuous infusion with 20% lipid injectable emulsion (ILE) 250 mL/day co-infused with the PN.

Pertinent Data:

- Height: 6 ft, 1 in (185 cm)
- Admission weight: 71 kg (156.5 lb)
- Weight 2 months prior to admission: 84 kg (185 lb)
- Present weight: 74 kg (163 lb)

1. Which of the following PN regimens is the *best* to initiate for this patient?

   A. Goal estimated caloric and protein requirements beginning PN day 1

   B. 100% Dextrose calories on PN day 1 and advance protein dose over 3 to 4 days

   C. 100 to 150 g Dextrose on PN day 1 and advance by 33% of goal to the goal regimen every 1 to 2 days until goal regimen is achieved

   D. 75% to 100% calculated caloric requirements PN day 1 and cycle the infusion over 16 hours

2. What is the daily amount of protein in grams provided by this patient's goal regimen?

   A. 60 g

   B. 71 g

   C. 86 g

   D. 108 g

3. What is the daily amount of dextrose in grams provided by this patient's goal regimen?

   A. 150 g

   B. 242 g

   C. 360 g

   D. 410 g

4. What is the approximate daily amount of nitrogen in grams provided by this patient's goal regimen?

   A. 12 g

   B. 17 g

   C. 25 g

   D. 34 g

5. What volumes of 10% amino acids and 70% dextrose stock solutions are required to provide daily protein and carbohydrate amounts for the goal regimen?

   A. 108 mL amino acids; 200 mL dextrose

   B. 540 mL amino acids; 275 mL dextrose

   C. 720 mL amino acids; 360 mL dextrose

   D. 1,080 mL amino acids; 514 mL dextrose

6. What is the daily total calories (energy) provided by the patient's goal PN regimen?

   A. 1,420 kcal (5941 kJ)

   B. 1,820 kcal (7515 kJ)

   C. 2,156 kcal (9021 kJ)

   D. 2,552 kcal (10678 kJ)

7. What is the total daily amount of ILE provided by the patient's goal PN regimen?

   A. 50 g

   B. 60 g

   C. 110 g

D. 250 g

8. Given the patient's current clinical status and therapeutic regimen, what is the *most* appropriate intervention to make at this time?

   A. Reduce the PN infusion rate to 35 mL/hr

   B. Discontinue the ILE

   C. Reduce the amino acid concentration to 4.25%

   D. Increase the dextrose concentration to 30%

9. Which statement is *true* regarding ILE when administered with a two-in-one PN formulation?

   A. Used to prevent fatty acid deficiency

   B. Usually the major source of calories in a PN regimen

   C. Should be infused as a single bag for no longer than 24 hours

   D. Cannot be administered via a peripheral vein

10. What is the rationale for cysteine addition to neonatal PN formulations?

    A. Increase pH of PN formulations

    B. Provide a conditionally essential nutrient

    C. Improve long chain fatty acid utilization

    D. Extend the beyond use date

11. Which of the following combinations of additives in a PN solution that provides 105 g amino acids and 350 g dextrose in 1,920 mL/day is *most likely* to result in an incompatibility?

    A. Sodium phosphate 40 mmol/L, calcium gluconate 5 mEq/L (2.5 mmol/L), and sodium bicarbonate 50 mEq/L (50 mmol/L)

    B. Potassium phosphate 60 mmol/day, calcium gluconate 10 mEq/day (5 mmol/day), and sodium acetate 125 mEq/day (125 mmol/day)

    C. Potassium phosphate 20 mmol/L, magnesium sulfate 8 mEq/L (4 mmol/L), and ranitidine 150 mg/day

    D. Magnesium sulfate 32 mEq/day (16 mmol/day), calcium gluconate 10 mEq/day (5 mmol/day), and cysteine 160 mg

12. What is the United States Pharmacopeia–assigned beyond use date for PN formulations?

    A. 30 hours at room temperature; 9 days refrigerated

    B. 36 hours at room temperature; 12 days refrigerated

    C. 48 hours at room temperature; 7 days refrigerated

    D. 48 hours at room temperature; 14 days refrigerated

13. Which statement is *true* regarding nutrition support in a very low birth weight premature neonate?

    A. Dextrose should be initiated at 14 mg/kg/min

    B. Protein should be initiated within the first 24 hours of life

C. ILE should be withheld for the first day of PN support

D. Fluid should be initiated at 50 mL/kg/day

14. A 6-week-old infant who was born at 28 weeks of gestation weighs 2 kg and has been receiving PN since birth. The infant's hospital course is significant for necrotizing enterocolitis that required an extensive small bowel resection. The infant is now 1 week post-surgery and is not receiving any enteral feedings. The morning laboratory measurements are noteworthy for a direct bilirubin concentration of 3.2 mg/dL (54.7 µmol/L) and elevated aminotransferases. All other laboratory measurements are within normal limits. PN was initiated and the regimen provides (final concentrations) 2.5% amino acids, 15% dextrose, with standard electrolytes, minerals, vitamins and trace elements infusing at 10 mL/hr continuous infusion and 20% ILE infusing at 1.3 mL/hr. Which of the following interventions is *most appropriate* regarding this infant's PN regimen?

A. Increase dextrose to 17%; decrease ILE rate to 0.8 mL/hr

B. Increase dextrose to 20%; continue same ILE

C. Decrease dextrose to 12.5%; decrease ILE to 0.5 mL/hr

D. Continue same dextrose; increase ILE to 1.5 mL/hr

15. A product shortage of injectable cysteine has been announced and is expected to continue for at least the next 6 months. Which of the following is a rational consideration to ensure PN safety for pediatric patients requiring cysteine-supplemented PN during the shortage?

A. None, because cysteine is not usually added to pediatric PN formulations

B. All two-in-one admixtures should be converted to TNAs

C. Calcium and phosphate solubility limits must be reassessed for PNs previously formulated with cysteine

D. PN CAA doses must be increased to accommodate cysteine loss

SELF-ASSESSMENT QUESTION-ANSWERS

1. **C.** According to the ASPEN Consensus Recommendations for Refeeding Syndrome (ASPEN CRRS), the patient has two diseases and clinical conditions associated with an increased risk of refeeding syndrome, cancer and postoperative patients with complications. The patient also has clinical features consistent with criteria for Significant Risk for developing refeeding syndrome. The patient's weight loss history exceeds the 7.5% in 3 months criteria (~15% weight loss over 2 months prior to admission). The patient had none or negligible oral intake for greater than 7 days, as well. ASPEN CRRS recommendations include initiating PN with 100 to 150 g of dextrose or 10 to 20 kcal/kg (42-84 kJ/kg) for the first 24 hours and advance by 33% of goal every 1 to 2 days. This includes enteral as well as other sources of parenteral dextrose such as maintenance IV fluids or medications administered in dextrose-containing IV fluids. Delaying PN initiation or advancing dextrose dose after PN initiation should be considered in patients with moderate-to-high risk of RS with low electrolyte levels until normal serum concentrations are achieved.

2. **D.** Total daily PN volume = 75 mL/hr × 24 hr = 1,800 mL or 1.8 L; amino acids 6% = 6 g/100 mL = 60 g/L; 60 g/L × 1.8 L = 108 g Protein.

3. **C.** Total daily PN volume = 75 mL/hr × 24 hr = 1,800 mL or 1.8 L; Dextrose 20% = 20 g/100 mL = 200 g/L; 200 g/L × 1.8 L = 360 g Dextrose.

4. **B.** 1 g Nitrogen = 6.25 g protein; 108 g protein ÷ 6.26 g protein/1 g nitrogen = 17.28 g nitrogen.

5. **D.** First, determine the appropriate volume of 10% CAA: 10% AA = 10 g/100 mL; 10 g/100 mL = 108 g/X mL 10% CAA; X = 1,080 mL 10% CAA; next, determine 70% dextrose volume: 70% dextrose = 70 g/100 mL; 70 g/100 mL = 360 g/X mL 70% dextrose; X = 514 mL 70% dextrose.

6. **C.** Protein calories = 108 g CAA × 4 kcal/g = 432 kcal; dextrose calories = 360 g dextrose × 3.4 kcal/g = 1,224 kcal; 20% ILE calories = 250 mL × 2 kcal/mL = 500 kcal; 2,156 kcal. Multiply values expresed in units of kcal by 4.18 for equivalent values in kJ.

7. **C.** 20% 250 mL ILE provided by PN regimen: 20 g/100 mL = X g/250 mL, X = 50 g; ILE provided by propofol: 25 mL/hr × 24 hr = 600 mL/day; propofol

contains 10% ILE, 10 g/100 mL = X g/600 mL, X = 60 g; 50 g + 60 g = 110 g/day total ILE.

8. **B.** Sufficient calories and essential fatty acids are provided by the daily propofol dose, so additional ILE is not necessary and results in total daily calories that exceed estimated requirements. Distractors A and C result in a PN regimen that provides insufficient protein. Distractor D results in a PN regimen that provides excessive dextrose.

9. **A.** ILE is a source of essential fatty acids and is used as a part of PN regimens to provide calories and to prevent or treat essential fatty acid deficiency. ILE is rarely the major source of calories, particularly in critically ill patients. While some ILE products are FDA approved to provide up to 60% total calories, maintaining a weight-based dose has been recommended that usually provides less than approximately 30% to 50% total calories. ILE may be administered in its original packaging for less than 12 hours or as a part of total nutrient admixture which may infuse up to 24 hours. ILE may be administered via peripheral or central venous access device because they are isotonic solutions.

10. **B.** Cysteine is a conditionally essential nutrient in infants due to enzymatic immaturity of the trans-sulfuration pathway (eg, biosynthesis of taurine). In addition to protein supplementation to the primary parenteral protein source, the addition of cysteine to PN solutions decreases solution pH thereby improving calcium and phosphate solubility.

11. **A.** Bicarbonate salts should be avoided in PN admixtures to avoid potential for precipitation of multiple salts including calcium and magnesium.

12. **A.** According to the current USP 797 guidelines, PN admixtures are considered Medium Risk compounded sterile preparations (CSPs), which have a 30-hour beyond use date (BUD) at room temperature and 9 day BUD refrigerated.

13. **B.** When initiating PN support in neonates and infants, all macronutrients should be given on day 1 (and optimally protein should be given within the first 24 hours of life for very low birthweight premature neonates). Dextrose and ILE are advanced daily over several days to achieve goal calories. Goal protein doses should be given from day 1. Dextrose is generally started at 6 to 8 mg/kg/min and advanced by 2 to 4 mg/kg/min to a goal of 10 to 14 mg/kg/min. ILE are started at 0.5 to 1 g/kg/day and advanced by 0.5 to 1 g/kg/day to a goal of 3 g/kg/day. PN is prescribed to provide daily fluid requirements (150 mL/kg/day in premature neonates).

14. **A.** Phytosterol content of SO-based ILE have been associated with the development of PN associated liver disease (PNALD) or cholestasis. Dose reduction of SO-based ILE is a potential treatment option for PNALD. An ILE rate of 1.3 mL/hr in a 2 kg infant provides 3.1 g/kg/day which is slightly above the maximum recommended dose of 3 g/kg/day. Reducing the ILE rate to 0.8 mL/hr decreases the daily ILE dose to 1.9 g/kg/day which is an appropriate initial dose reduction. Dextrose calories should be increased to offset the reduction in calories from the ILE. An increase from 15% (12.5 mg/kg/min) to 17% dextrose (14 mg/kg/min) provides additional calories without exceeding the maximum dextrose requirements for this patient.

15. **C.** Cysteine may be added to PN solutions as a conditionally essential amino acid due to enzymatic immaturity of the trans-sulfuration pathway in neonates and infants. Cysteine also decreases PN solution pH thereby improving calcium and phosphate solubility. If cysteine is removed from a PN solution, the calcium and phosphate solubility curve must be reassessed to ensure solubility limits are not exceeded. There is no need to increase the dose of CAA when removing cysteine from PN solutions as its addition only provides a negligible amount of protein.

Chapter 166: Enteral Nutrition

Diana W. Mulherin

KEY CONCEPTS

KEY CONCEPTS

① The gastrointestinal (GI) tract defends the host from toxins and antigens by both immunologic and nonimmunologic mechanisms, collectively referred to as the gut barrier function. Whenever possible, enteral nutrition (EN) is preferred over parenteral nutrition (PN) because it is associated with a lower risk of metabolic and infectious complications and is less expensive and invasive.

② Candidates for EN are those with a sufficiently functioning GI tract to allow adequate nutrient absorption who cannot or will not eat and in whom enteral access can be safely obtained.

③ Critically ill patients benefit from early initiation of EN. It is acceptable to deliver EN at low rates (eg, trophic feeds) for the first week in most ICU patients. However, this method may not be appropriate for severely malnourished patients who should have their EN advanced to goal as quickly as tolerated.

④ The most common route for both short- and long-term EN access is directly into the stomach. The method of delivery may be continuous via an infusion pump, intermittently via a pump or gravity drip, or bolus administration via gravity or syringe.

⑤ Patients unable to tolerate tube feeding into the stomach because of impaired gastric motility may benefit from feeding tube placement into the duodenum or jejunum. When feeding into the small bowel, the continuous method of delivery via an infusion pump is required to enhance tolerance.

⑥ Selection of the enteral feeding formulation depends on nutritional requirements, the patient’s primary disease state and related complications, and nutrient digestibility and absorption. A standard polymeric formulation is appropriate for the majority of adults.

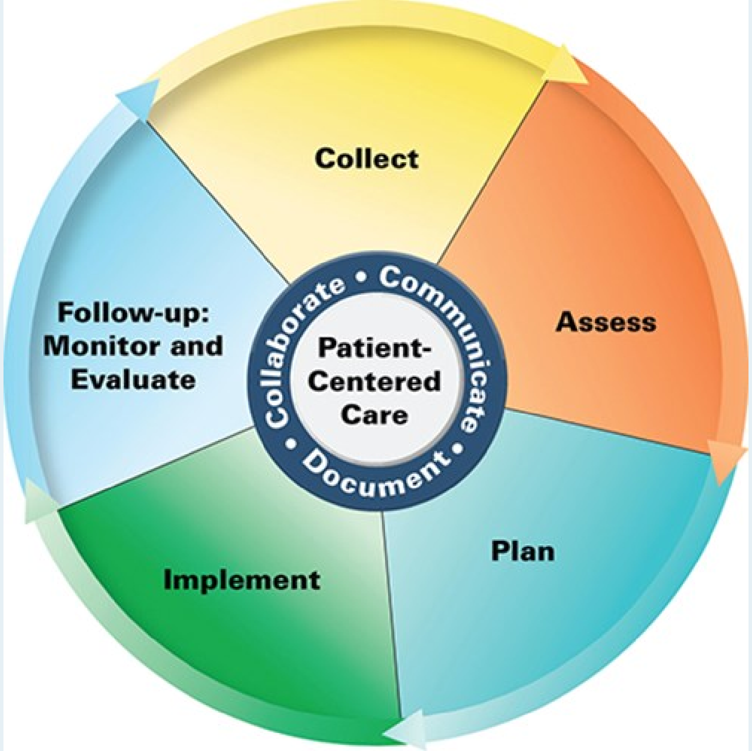
⑦ Management of diarrhea in patients receiving EN should focus on identification and correction of the most likely cause(s). Tube feeding-related causes include too rapid delivery or advancement, intolerance to the formula composition, and occasionally formula contamination.

⑧ Medication administration through a feeding tube requires selection of an appropriate dosage form and verification of appropriate enteral access. Medications that should not be crushed and administered through a tube include enteric-coated or sustained-release capsules or tablets and sublingual or buccal tablets.

⑨ The coadministration of medications with EN can result in alterations in bioavailability and/or changes in the desired pharmacologic effects. Numerous medications are known to interact with EN including phenytoin, warfarin, levothyroxine, select antimicrobials, antacids, and proton-pump inhibitors.

PATIENT CARE PROCESS

Patient Care Process for the Use of Enteral Nutrition



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient characteristics (eg, age, sex)
- Patient history (past medical, surgical, family, social – alcohol use)
- Nutrition history (dietary history, weight history, dietary intolerance, prior enteral, or parenteral nutrition therapy)
- Current medications (including nutritional supplements)
- Current diet and current nutrition support regimen
- Procedures related to enteral access placement
- Objective data
  - Height, weight, body mass index (BMI)
  - Fluid balance (intake and output)
  - Labs (eg, serum electrolytes, SCr, blood urea nitrogen [BUN], glucose, albumin)
  - Other diagnostic tests when indicated (eg, abdominal imaging, gastric emptying study, swallow study)

Assess

- Appropriate time to initiate EN
- Presence of altered GI anatomy or function (eg, intestinal surgeries, delayed gastric emptying, pancreatic insufficiency)
- Nutritional status and risk of refeeding syndrome (eg, unintentional weight loss, prolonged-time period with poor nutritional intake, BMI <18 kg/m^2, low visceral proteins, muscle wasting)

- Nutrition requirements (goal protein, calories, fluid, and micronutrient intake)
- Appropriate enteral access (see Table 166-3)

Plan

- EN regimen includes specific enteral feeding formulation, method of administration (continuous, bolus), and initiation and advancement guidelines (see Table 166-5).
- Monitoring parameters for efficacy (weight, enteral intake), GI tolerance (stool output, nausea, vomiting, abdominal distension), and metabolic complications (serum electrolytes, SCr, BUN, glucose, liver function tests [LFTs]; see Table 166-6).

Implement

- Initiate EN when the oral route fails or is not possible, the GI tract is functional, and enteral access can be safely achieved
- Patient education when home EN is indicated

Follow-up: Monitor and Evaluate*

- Determine nutrition goal attainment
- Provide adjustments to the EN regimen when nutrition goals are not achieved and consider transition to PN if repeated adjustments fail or intolerance develops
- Transition off EN when nutrition needs are safely met by oral dietary intake
- Presence of adverse medication reactions and GI intolerance
- Plan for transitioning off EN

**Collaborate with patient, caregivers, and other health professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Visit the “Feeding Tube Awareness Foundation” website <https://www.feedingtubeawareness.org> and navigate to “Tube Feeding Basics.” The webpage contains information on each type of feeding tube. The information is presented in a patient education format and is useful to enhance student understanding of the types of feeding tubes available, how these appear when inserted into a patient, and general clinical and patient considerations for each tube. This will aid in the COLLECT and ASSESS steps in the patient care process.

INTRODUCTION

Enteral nutrition (EN) is defined as the delivery of nutrients by tube or by mouth into the gastrointestinal (GI) tract. This chapter focuses on nutrient delivery through a feeding tube rather than oral food ingestion. The terms *enteral nutrition* and *tube feeding* are thus used interchangeably in this context. The goal of EN is to provide calories, macronutrients, and micronutrients to those patients who are unable to achieve these requirements from an oral diet. Increased recognition of malnutrition, along with improvements in enteral access techniques, feeding formulations, and methods to prevent and manage complications, have resulted in an increased use of EN across all healthcare settings. In this chapter, principles and practices related to the safe and successful use of EN therapy are described.

GASTROINTESTINAL TRACT PHYSIOLOGY

The GI tract plays a key role in the processing of ingested foods. Many of the processes involved in digestion, absorption, and utilization of nutrients are modifiable by the presence of acute and chronic illnesses.

Digestion and Absorption

Digestion and absorption are GI processes that generate the body's usable fuels.[1,2] Ingested nutrients are primarily large polymers that cannot be absorbed across the intestinal cell membrane unless they are transformed into an absorbable molecular form. Digestion consists of the stepwise conversion of a complex chemical and physical nutrient into a molecular form that is absorbable by the intestinal mucosa.[1] Absorption from the GI tract is a multistep process that includes the transfer of a nutrient across the intestinal cell membrane. The nutrient ultimately reaches the systemic circulation through the portal venous or splanchnic lymphatic systems, provided that the GI or biliary tract does not excrete it. In addition, a coordinated interplay of GI motility and neurohormonal secretion is required to facilitate adequate digestion and absorption.

Nutrient digestion involves the complex coordination of multiple mechanical, enzymatic, and physiochemical processes.[1,2] Mechanical dissolution of food occurs by chewing, then mixing and grinding the stomach contents. Food stimulates the secretion of numerous hormones and enzymes from the salivary glands, stomach, liver and biliary system, pancreas, and intestines (Table 166-1). As food traverses the gut lumen, these hormones modulate GI motility and the secretions from other organs of the digestive system. Nutrient absorption occurs within the gut lumen and is a specific function of the intestinal cell membrane, which is comprised of fingerlike projections called villi. Each individual villus is made up of epithelial cells called enterocytes. The enterocyte surface contains special luminal projections called microvilli, which provide an increased surface area that is referred to as the brush-border membrane.

TABLE 166-1

Gastrointestinal Enzymes and Hormones

Enzyme/Hormone	Site of Secretion	Main Actions
Amylase	Salivary glands, pancreas	Converts carbohydrates, starch, and glycogen to simple disaccharides
Cholecystokinin	Duodenum, jejunum	Stimulates pancreatic enzyme secretion and gallbladder contraction
Chymotrypsinogen	Pancreas	Breaks down proteins into peptides
Enteroglucagon	Duodenum, small intestine	Inhibits pancreatic enzyme secretion and bowel motility
Gastric inhibitory peptide	Small intestine	Decreases gastric motility and stimulates insulin secretion
Gastrin	Stomach, duodenum	Stimulates gastric acid secretion and mucosal growth
Glucagon	Pancreas	Stimulates hepatic glycogenolysis and inhibits motility
Lipase	Pancreas	Hydrolyzes dietary fat to release fatty acids
Pancreatic polypeptide	Pancreas	Inhibits gallbladder contraction and pancreatic and biliary secretion
Pepsinogen	Stomach	Converts large proteins into polypeptides
Secretin	Small intestine	Stimulates hepatic and pancreatic water and bicarbonate release
Trypsinogen	Pancreas	Breaks down proteins into peptides
Vasoactive inhibitory peptide	Small intestine, pancreas	Vasodilator; stimulates water and bicarbonate secretion, insulin and glucagon release, and small bowel secretions

The digestion and absorption of carbohydrates, fat, and protein within the small intestine are illustrated in Fig. 166-1. Carbohydrates are presented to the small intestine in either a digestible or a nondigestible form. Polysaccharides (starches) and oligosaccharides (sucrose and lactose) undergo enzymatic digestion to simple sugars. The simple sugars are absorbed via active and passive transport mechanisms and are eventually released into the portal vein. Polysaccharides, such as cellulose complexes and other fiber components, pass undigested to the colon, where they are digested by bacteria and enzymes to short-chain fatty acids. Colonic absorption of short-chain fatty acids stimulates sodium and water reabsorption. The short-chain fatty acids serve as a systemic energy source and provide nourishment for the colonic mucosa cells.

Fat is most often presented to the small intestine as long-chain triglycerides. Fat digestion requires pancreatic lipase release and formation of mixed bile salt micelles, which are then absorbed across the intestinal enterocyte. Within the enterocyte, triglycerides are reesterified and packaged into chylomicrons that are then transported into the lymphatic system. Medium-chain triglycerides (MCTs) can be absorbed intact by the mucosal membrane and are acted on by intracellular lipase within the enterocyte to release free fatty acids that pass directly into the portal vein.[3]

Protein is presented to the small intestine primarily as large polypeptides and to a lesser extent as free amino acids because of protein denaturation in the stomach. Polypeptide digestion generates oligopeptides, which are further hydrolyzed to dipeptides and tripeptides. Peptide absorption occurs via a peptide transport system while free amino acids are absorbed via specific amino acid transporters. These peptide carriers are efficient, whereas free amino acid absorption is efficient.[2]

Understanding the mechanisms involved in digestion and absorption can greatly enhance the rational use of EN in patients with normal or altered GI anatomy and/or function. Various circumstances may alter the efficacy of nutrient digestion and absorption. For example, pancreatic insufficiency may result in malnutrition associated with inadequate absorption of fat and fat-soluble vitamins.

Gut Host Defense Mechanisms

① Besides digesting and absorbing nutrients to maintain nutritional health, the GI tract is actively involved in defending the host from toxins and antigens by both immunologic and nonimmunologic mechanisms.[4] These gut host defense mechanisms are collectively referred to as the gut barrier function. The gut barrier acts to prevent the systemic spread of intraluminal bacteria and endotoxins to other organs and tissues. Hydrochloric acid secreted by the stomach kills most of the bacteria ingested with food. Under normal circumstances, a mucus layer coats the intestinal epithelium and thereby alters the adherence of bacteria to the cells of the GI tract but provides a favorable environment for anaerobic bacteria. Anaerobic bacteria, which normally colonize the mucus layer, aid in preventing tissue colonization by potential pathogens. Small bowel peristalsis further prevents bacterial stasis and overgrowth. The gut barrier function is also maintained by the intestinal immune system, known as the gut-associated lymphoid tissue (GALT). GALT regulates the local immune response to antigens within the GI tract. Specific immunoglobulins are secreted to kill the remaining organisms and neutralize any toxins they produce. The liver Kupffer cells help to maintain gut barrier function by clearing the portal blood of gut-derived bacteria and endotoxins. Gut barrier integrity may be affected negatively by numerous pathogenic insults, such as physiologic stress and ischemia, and a variety of medications, including chemotherapeutic agents. The administration of certain probiotics can modify intestinal flora and may have beneficial effects in various disease states and patient populations by positively affecting the maintenance of gut barrier function and intestinal immune function.[5,6]

INDICATIONS FOR ENTERAL NUTRITION

② The decision to initiate EN is based on a variety of factors. Suitable candidates are those who cannot or will not eat a sufficient amount to meet their nutritional requirements, those who exhibit a sufficient functioning GI tract to allow for nutrient absorption, and those in whom a method of enteral access can be safely initiated.[7,8] Thus, EN may be indicated in a variety of conditions or disease states (Table 166-2). For example, patients who have difficulty swallowing due to stroke, altered mental status, or obstruction in the head, neck, or esophagus due to cancer may benefit from EN.

TABLE 166-2

Potential Indications for Enteral Nutrition

Neoplastic disease • Chemotherapy • Radiation therapy • Upper GI tumors • Cancer cachexia **Organ dysfunction** • Liver disease/failure • Kidney disease/failure • Cardiac cachexia • ARDS/ALI • Bronchopulmonary dysplasia • Congenital heart disease • Organ transplantation **Hypermetabolic states** • Closed head injury • Burns • Trauma • Postoperative major surgery • Sepsis **GI disease** • Inflammatory bowel disease • Short bowel syndrome • Esophageal motility disorder • Pancreatitis • Fistulas • Gastroesophageal reflux disease (severe) • Esophageal or intestinal atresia	**Neurologic impairment** • Comatose state • Cerebrovascular accident • Demyelinating disease • Severe depression • Cerebral palsy **Other indications** • AIDS • Anorexia nervosa • Complications during pregnancy • Failure-to-thrive • Geriatric patients with multiple chronic diseases • Inborn errors of metabolism • Cystic fibrosis

AIDS, acquired immune deficiency syndrome; ALI, acute lung injury; ARDS, acute respiratory distress syndrome

Critically ill patients who are endotracheally intubated represent a large percentage of hospitalized patients requiring EN. Traditionally, EN in the critically ill population was regarded as supportive care designed to provide nutrients during the period of time the patient was unable to maintain adequate oral dietary intake. EN may also be used as a tool to modulate the stress response to critical illness and improve patient outcomes. Nutrition guidelines support the initiation of EN in critically ill adults who are unable to maintain volitional intake, and this can usually be achieved by feeding directly into the stomach.[9–11] Some of these patients may have reduced gastric emptying caused by sepsis, GI surgery, anesthetic agents, opioid analgesics, and underlying pathology, such as diabetic gastroparesis and burns. However, successful EN can often still be achieved by advancing the tip of the feeding tube beyond the pylorus into the duodenum, or preferably into the jejunum. Small bowel feeding may also be appropriate for patients with gastric outlet obstruction, those with pancreatitis, those with moderate-to-severe gastroesophageal reflux, or those with high aspiration risk.

Contraindications to EN use are distal mechanical intestinal obstruction, bowel ischemia, and necrotizing enterocolitis. Contraindications to tube placement include active peritonitis and uncorrectable coagulopathy.[1,12] Conditions that may result in challenges to EN use include severe diarrhea, protracted vomiting, enteric fistulas, severe GI hemorrhage, hemodynamic instability, and intestinal dysmotility.

BENEFITS OF ENTERAL NUTRITION

The importance of maintaining nutrient delivery through the GI tract in patients without a contraindication to its use is well supported. The beneficial effects of EN, specifically in the critically ill patient, are further enhanced if EN is initiated within 24 to 48 hours of admission to an intensive care unit (ICU).[9–11]

Enteral Versus Parenteral Nutrition

Historically, comparisons of EN and parenteral nutrition (PN) in critically ill adult patients have demonstrated a decrease in infectious complications with the use of EN.[13] Infectious complications are thought to be less common with EN in part because EN supports functional gut integrity by stimulating bile flow and the release of endogenous trophic agents, such as cholecystokinin, gastrin, and bile salts. Provision of enteral nutrients help maintain the intestinal mucosal villous height and support the mass of secretory immunoglobulin A (IgA)-producing immunocytes that comprise the GALT. In the setting of critical illness or severe injury, adverse changes in gut permeability and gut barrier function that result in increased risk for systemic infection and multiorgan dysfunction syndrome have been noted. By supporting gut integrity, the enteral feeding route is thought to lower infection risk and minimize organ failure.[9]

The use of EN in patients with abdominal trauma, burns, severe head injury, major surgery, and acute pancreatitis is generally thought to lower infectious complications compared to PN. This reduction in infectious complications is primarily associated with a lower incidence of pneumonia and catheter-related bloodstream infections and a decrease in abdominal abscess in trauma patients.[13] However, the use of EN as the preferred route for early nutritional support in critically ill patients has been challenged.[14–16] EN is more physiologic than PN in terms of nutrient utilization and therefore is generally associated with fewer metabolic complications, such as glucose intolerance and elevated insulin requirements.[17] Enteral formulations contain both complex and simple carbohydrates, which results in slower carbohydrate absorption compared with the simple carbohydrate, dextrose, used in PN. In addition, enteral formulations that contain fiber and/or a high-fat content will further slow carbohydrate absorption and reduce blood glucose elevations by delaying gastric emptying, accounting for better blood glucose control when carbohydrates are given via the enteral route. An additional physiologic benefit of enteral feeding is that it stimulates bile flow through the biliary tract and thus reduces the risk of developing cholestasis, gallbladder sludge, and gallstones, conditions that have been associated with long-term PN and bowel rest.[18] EN avoids the potential infectious and technical complications associated with the placement and the use of a central venous access device required for PN. Finally, EN is less costly than PN when all factors associated with the therapy are considered.

Timing of Initiation

The timing of initiation of EN in the critically ill patient is of clinical significance. Initiating EN in the first 24 to 48 hours following admission to the ICU is associated with decreased disease severity and infectious complications when compared with the initiation of feedings after 48 hours.[9–11] Early EN has also been associated with a decrease in the release of inflammatory cytokines and fewer effects on gut permeability.[9] In addition, a trend toward reduction in mortality associated with early EN has been noted.[9–11]

In critically ill patients who are hemodynamically unstable, there is concern that EN may result in bowel necrosis because of poor gastric perfusion and increased oxygen demand. It is recommended that initiation of EN be delayed until the patient is fluid resuscitated and vasopressors are being withdrawn or are infusing at low, stable doses.[9] EN is well-tolerated in patients receiving lower doses of vasopressors, and early EN has been associated with decreased mortality in patients receiving vasopressors.[19,20] Therefore, early EN (within 24-48 hours after hospital admission) can safely be initiated in most critically ill adult patients.[9–11] Early EN initiation is not warranted for previously well-nourished, mild to moderately stressed adult patients who are not critically ill. When oral intake is inadequate, it is reasonable to delay the initiation of EN for 5 to 7 days in these patients.[7] In the mild-to-moderately stressed adult patient who is moderately to severely malnourished, most clinicians would initiate EN sooner.

ENTERAL ACCESS

Advances in enteral access techniques have contributed to the expanded use of EN for conditions in which PN had previously been used. In particular, improved methods of achieving jejunal access for feeding have allowed the use of EN during the early postoperative and post-injury period when gastric motility is typically impaired. As outlined in Table 166-3, various factors influence the selection of enteral access site and device, including anticipated duration of use and whether to feed into the stomach or small bowel. Figure 166-2 illustrates the predominant enteral access options.

FIGURE 166-2

Access sites for tube feeding.

TABLE 166-3

Options and Considerations in the Selection of Enteral Access

Access	EN Duration/Patient Characteristics	Tube Placement Options	Advantages	Disadvantages
Nasogastric or orogastric	Short-term Intact gag reflex Normal gastric emptying	Manually at bedside	Ease of placement Allows for all methods of administration Inexpensive Multiple commercially available tubes and sizes	Potential tube displacement Potential increased aspiration risk
Nasojejunal	Short-term Impaired gastric motility or emptying High risk of GER or aspiration	Manually at bedside Fluoroscopically Endoscopically	Potential reduced aspiration risk Allows for early postinjury or postoperative feeding Multiple commercially available tubes and sizes	Manual transpyloric passage requires greater skill Potential tube displacement or clogging Bolus or intermittent feeding not tolerated
Gastrostomy	Long-term Normal gastric emptying	Surgically Endoscopically Radiologically Laparoscopically	Allows for all methods of administration Low-profile buttons available Large-bore tubes less likely to clog Multiple commercially available tubes and sizes	Attendant risks associated with each type of procedure Potential increased aspiration risk Risk of stoma site complications
Jejunostomy	Long-term Impaired gastric motility or gastric emptying High risk of GER or aspiration	Surgically Endoscopically Radiologically Laparoscopically	Allows for early postinjury or postoperative feeding Potential reduced aspiration risk Multiple commercially available tubes and sizes Low-profile buttons available	Attendant risks associated with each type of procedure Bolus or intermittent feeding not tolerated Risk of stoma site complications

EN, enteral nutrition; GER, gastroesophageal reflux

Short-Term Access

③ Short-term enteral access is easier to initiate, less invasive, and less costly than the establishment of long-term access.[21] The most frequently used routes for short-term enteral access are established by inserting a tube through the nose or mouth and passing the tip into the stomach (nasogastric [NG], orogastric [OG]), or jejunum (nasojejunal [NJ], orojejunal [OJ]). In general, these tubes are used in the hospitalized patient when the anticipated tube feeding duration is less than 4 to 6 weeks. The orogastric route is generally reserved for patients in whom the nasopharyngeal area is inaccessible. Because these routes do not require surgical intervention, they are the least invasive options. The most common technique for placement is blind passage at the bedside by trained medical personnel. Several techniques have been described in the literature to help facilitate bedside placement, and greater skill is required to advance the tip of the feeding tube beyond the pylorus and into the small bowel.[12] Metoclopramide, a prokinetic agent, has been used with variable success to aid passage of the tube beyond the pylorus. A bedside electromagnetic tube placement device has also been used to guide tip position into the small bowel by attracting a metal tip on the end of the tube.[22,23] Alternatively, a variety of endoscopic and fluoroscopic techniques have been described to insert tubes into the small bowel.[12,21] Radiographic confirmation of appropriate tip placement should be obtained prior to use for all bedside placed feeding tubes.[12,24]

NG tubes vary in diameter and stiffness. Large-bore (greater than or equal to 14F) rigid NG tubes are used primarily to decompress the stomach (eg, removal of gas and fluid in the setting of an ileus or obstruction) but can also be used for feeding. There is a low incidence of clogging with these tubes, and they provide a reliable way to measure gastric residual volumes (GRVs). The major disadvantages associated with the use of these tubes are patient discomfort and the risk of irritation or trauma to the gastric mucosa. Small-bore nasal tubes designed solely for feeding are available in varying lengths (12-60 inches [30-152 cm]) and diameters (3.5F-12F) to accommodate both pediatric (including neonates) and adult patients. The tip of the tube can be placed into the stomach or into the duodenum or jejunum (also referred to as transpyloric placement). These tubes consist of a lightweight, pliable silicone or polyurethane material that is designed for patient comfort. A disadvantage of small-bore tubes is that they more easily occlude, often as a result of improper medication administration or flushing technique. The feeding tube is frequently held in place only by a piece of tape on the nose or face; therefore, it can be inadvertently dislodged relatively easily. Nasal bridles have been used with variable results to secure the nasoenteric tube in place.[12] A bridle involves passing a piece of thin tubing or suture into one nostril, then around the bony portion of the nose, and out the other nostril, and finally tying the tubing around the feeding tube.

④ In general, gastric feeding is the least expensive and the least labor-intensive method for enteral feeding; however, feeding into the stomach is not always tolerated. Patients with impaired gastric motility may be predisposed to aspiration and pneumonia when fed into the stomach. Many critically ill, injured, and postoperative patients exhibit delayed gastric emptying, which limits their ability to tolerate gastric feeding. In addition, patients with diabetic gastroparesis or patients with severe gastroesophageal reflux disease or intractable vomiting are at a higher risk for aspiration of gastric contents, which can result in pneumonia. In these patients, placing the tip of the tube into the duodenum or jejunum may be used as a method to decrease aspiration risk.[12] Transpyloric feeding has been associated with a lower rate of vomiting and ventilator-associated pneumonia when compared to NG feeding. However, the difference in aspiration and aspiration pneumonia risk associated with gastric and small bowel feeding is inconclusive.[9] In general, small bowel feeding may be beneficial in patients who do not tolerate gastric feeding and offers an alternative option for EN prior to resorting to PN.[9–11]

Long-Term Access

Feeding tubes used for short-term enteral access are usually not optimal for long-term use because of patient discomfort, complications, and mechanical failures that develop over time. Long-term access should generally be considered when the need for EN is anticipated to be longer than 4 to 6 weeks. Many techniques can be used to establish long-term enteral access, including laparotomy, laparoscopy, endoscopic and image guidance (eg, fluoroscopy and ultrasound).[12] The ability to perform the various techniques is somewhat dependent on the expertise and facilities available within each institution. Long-term enteral access options include gastrostomy and jejunostomy tubes.

A gastrostomy is the most common type of long-term enteral access. It eliminates the nasal irritation and discomfort associated with nasoenteric feeding tubes and inadvertent removal is uncommon. In addition, because feeding gastrostomies use large-bore tubes, clogging is less of a problem. The most commonly placed is the percutaneous endoscopic gastrostomy (PEG). The technique is minimally invasive and can be performed safely and cost-effectively in an endoscopy suite or at the bedside using conscious sedation and local anesthesia in adult patients. Gastrostomy tubes are available in various sizes (12F-28F; 0.8-5 cm shaft lengths) and materials (eg, silicone and polyurethane) and have different retention mechanisms. Since smaller-diameter tubes are prone to more frequent occlusion and dysfunction, the largest diameter size possible is preferred. For patient convenience, comfort, and cosmetic appearance, a low-profile skin-level gastrostomy device may be used. It is typically placed as an exchange tube for a preexisting gastrostomy or jejunostomy once the tract has matured but can also be used at the time of initial tube placement. This "gastric button" consists of a short, silicone, self-retaining conduit with either a mushroom-type or a balloon-type tip at the internal end and a one-way valve and small flange at the skin surface. Because this averts the external tube presence, it tends to be preferred in children or ambulatory adults who are receiving intermittent feedings. The exit site of all gastrostomies requires general stoma care to prevent inflammation and infection. Routine replacement of the gastrostomy tube at defined intervals (usually 3-6 months) is a standard of practice of many clinicians to prevent failure of the retention mechanism that can occur over time.[12]

In patients with a functional bowel but impaired gastric motility, pancreatitis, or who otherwise do not tolerate gastric feeding and require long-term enteral access, a jejunostomy may be an appropriate option.[21] Various endoscopic and fluoroscopic techniques are available for direct jejunostomy placement. A surgically placed jejunostomy may also be an option. For patients who require small bowel feeding with simultaneous gastric decompression, a gastrojejunal (GJ) tube may be placed utilizing various endoscopic, fluoroscopic, and surgical techniques.[21] Because jejunostomies use smaller-bore tubes, occlusion occurs more commonly than with gastrostomy tubes. GJ tubes are often replaced every 3 to 6 months to prevent occlusion.

There are ethical implications regarding the determination of appropriate candidates for long-term feeding tube placement.[12,25–27] Because a gastrostomy is relatively easy to place and many patients, families, and clinicians overestimate the benefits of EN, it is prone to inappropriate use. In certain patient populations, such as those with advanced dementia or other near end-of-life conditions, the placement of a gastrostomy is not recommended. Artificial nutrition and hydration (ANH) do not promote the healing of pressure ulcers, increase patient comfort or functional status, or prolong survival when compared to hand feeding in patients with advanced dementia.[25] From a clinical standpoint, ANH does not increase a patient's comfort or improve the nutrition parameters of most terminally ill individuals and can result in medical complications.[25] Survival rates are not improved in older adults with advanced dementia who receive tube feedings, and it is associated with substantial burden, including agitation, greater use of physical and chemical restraints, recurrent aspiration, and tube-related complications.[26,27] Evaluation by a multidisciplinary team is warranted for all patients near the end of life to establish whether the benefit of EN outweighs the risks of feeding tube placement.[25–27]

ADMINISTRATION METHODS

EN may be administered by continuous, cyclic (continuous rate over a portion of the day), intermittent (infused over 20-60 minutes), or bolus (generally given in 5-10 minutes) methods and may be accomplished by syringe, gravity, or pump-controlled techniques. The delivery method depends on the location of the tip of the feeding tube, the patient's clinical condition and intestinal function, and the patient's tolerance to the tube feeding.

Continuous

Pump-assisted continuous administration of EN is generally the method of choice for most hospitalized patients, especially when initiating therapy. They may be candidates for transitioning to intermittent or bolus feeding for long-term use as their medical condition stabilizes, as described below. However, when EN is to be delivered into the small intestine, the continuous method is always preferred because it is associated with enhanced tolerance. The rapid delivery of feeding into the small intestine may contribute to abdominal distension, cramping, hyperperistalsis, and diarrhea. Therefore, conversion to intermittent or bolus administration is not recommended for those with jejunostomies.

The delivery system for continuous administration generally includes a feeding set with an attached reservoir bag or spike set that connects to a feeding container. The feeding set is attached to a pump and then connected to the patient's enteral access tube with an adaptor. Continuous administration may increase nursing time because routine checks are needed, but this disadvantage is usually offset by the improved tolerance. For adults, target EN administration rates generally range from 50 to 125 mL/hr, although this varies considerably based on the EN formula and specific needs of the patient. The primary disadvantage to this method of administration is the cost and inconvenience associated with the pump and administration sets. In the home care setting, battery-operated ambulatory enteral pumps that fit into a backpack with the feeding bag are available to allow the patient greater mobility.

Cyclic

A patient who is not eating well during the day because of complaints of fullness and lack of appetite or who is not able to consume enough calories during the day to meet increased needs (eg, trauma and burns) may benefit from cyclic EN, in which the enteral feeding is administered by pump during part of the day – this typically occurs at night. In addition, nocturnal EN administration will free the patient from the pump during the day and allow for greater mobility. This increased mobility may be particularly useful for the home patient or patient requiring therapy for physical rehabilitation during the day. This method may be used in patients with either gastric or small bowel access.

Bolus

The bolus administration of EN is commonly used for patients in the home or long-term care setting who have a gastrostomy. This administration technique involves the delivery of the enteral feeding formulation over 5 to 10 minutes. Essentially, the only equipment needed is a syringe to instill the feeding volume into the tube. Depending on the patient's nutritional requirements, a feeding volume of 240 to 500 mL is generally used and repeated four to six times daily. From a convenience standpoint, it is generally preferable to adjust the bolus volume in increments of the feeding formulation container size (usually 240-250 mL). Bolus delivery is not appropriate for patients with duodenal or jejunal access, as it may result in cramping, nausea, vomiting, aspiration, and diarrhea. Bolus administration should also be avoided in patients with delayed gastric emptying and in patients who are at high risk of aspiration.

Intermittent

The intermittent method is used in patients with a gastric feeding tube who may be experiencing intolerance to bolus administration over 5 to 10 minutes. In this scenario, the prescribed volume is administered over a longer duration, generally 20 to 60 minutes every 4 to 6 hours. For this method, the desired volume of feeding formulation is emptied into a reservoir bag or container with attached tubing and administered by an enteral pump or via gravity drip using a roller clamp. The bolus and intermittent methods of administration are more consistent physiologically with normal eating patterns compared to the continuous method.

INITIATION AND ADVANCEMENT PROTOCOL

Guidelines for the initiation and advancement of enteral feeding formulations vary greatly and are primarily tailored to patient tolerance. The typical recommendation for continuous EN administration for adults is to start at 20 to 50 mL/hr and advance by 10 to 25 mL/hr every 4 to 8 hours until the desired goal is achieved. For intermittent administration, the typical recommendation is to start with 120 mL every 4 hours and advance by 30 to 60 mL every 8 to 12 hours.[7] Schedules for progression of tube feeding from initial to target rates are important and may influence tolerance. If the protocol is too conservative, it may take an excessively long period of time to reach nutrient goals. The development of an EN protocol within an institution that outlines initiation and advancement criteria is recommended to optimize achievement of nutrient goals.[9,11] Due to frequent interruptions of EN, some institutions have implemented volume-based feeding protocols to improve success in meeting targeted goals. Such a protocol shifts the focus from an hourly rate target goal to a 24-hour volume goal and provides guidance on how to adjust the rate of administration when EN is interrupted for reasons unrelated to GI tolerance such as surgeries or procedures.[28,29]

The optimal dose of EN in critically ill adult patients is a subject of debate. The intentional use of permissive underfeeding (50%-80% of goal) or trophic EN (10-20 mL/hr) in critically ill adult patients requiring short ICU lengths of stay may result in improved GI tolerance and similar short-term outcomes when compared to full feeding.[9] However, the strategy of intentional underfeeding may not be appropriate for patients at high nutrition risk as defined by validated scores accounting for nutrition status, disease severity, preexisting malnutrition, and co-morbidities. Patients who are severely malnourished or at high nutrition risk should have their EN advanced toward their energy goal over 24 to 48 hours while monitoring for refeeding syndrome. This is due to an association with lower mortality in critically ill patients at high nutrition risk who receive adequate nutrition.[9,30]

WATER FLUSHES

All feeding tubes require routine flushing with water before and after administration of EN and medications.[24] Flushing may be done manually with a syringe or via the tube feeding pump. Feeding tubes should be flushed immediately before and after bolus or intermittent feedings and at standard intervals (eg, a minimum of 30 mL every 4 hours) with continuous feedings. Safe drinking water is an appropriate flushing source for most patients. Purified water is the preferred flushing source for immunocompromised or critically ill patients. Any fluid needs unmet by the tube feeding formula itself can be achieved via tube feeding water flushes.[24]

ENTERAL FEEDING FORMULATION SELECTION

Historically, enteral formulas were designed primarily to provide essential nutrients. Over the years, enhancements have been made to meet specific patient needs and improve tolerance. For example, nutrient composition has been enhanced by changing the content of the amino acids (eg, glutamine and arginine), increasing the omega-3 polyunsaturated fatty acid content, and adding ribonucleic acid (RNA) to enhance immune function and improve therapeutic outcomes. These specific nutrients have been called pharmaconutrients or immunonutrients because of the intent to use them to modify the activity of the immune system and improve clinical outcomes.[31] Enteral feeding formulations are categorized by the Food and Drug Administration (FDA) as medical foods.[32] They are considered components of supportive care and are simply regulated to ensure sanitary manufacture. Unfortunately, they are not subject to rules governing health claims, and the promotion of medical foods for therapeutic intent is not regulated by the FDA.[32]

The macronutrient content of enteral formulas (namely, protein, carbohydrate, and fat) varies in nutrient complexity (Table 166-4). Nutrient complexity refers to the amount of hydrolysis and digestion a substrate requires prior to intestinal absorption. Polymeric or intact substrates are of similar molecular form as the foods we eat. Enteral formulas that contain partially hydrolyzed or elemental substrates are characterized as elemental or defined-formula diets. The caloric contribution of each of the macronutrients is as follows: carbohydrates, 4 kcal/g (17 kJ/g); protein, 4 kcal/g (17 kJ/g); and fat, 9 kcal/g (38 kJ/g).

TABLE 166-4

Enteral Formula Nutrient Complexity

Nutrient	Polymeric or Intact	Partially Hydrolyzed or Elemental
Carbohydrate	• Starches • Fruit, vegetable, cereal solids • Glucose polymers • Corn syrup solids • Polysaccharides	• Oligosaccharides • Maltodextrins • Disaccharides • Maltose, sucrose, lactose • Monosaccharides • Glucose • Galactose
Fat	• Long-chain triglycerides • Polyunsaturated fatty acids • Corn oil • Safflower oil • Soybean oil • Canola oil • Marine oils	• Medium-chain triglycerides • Coconut oil • Palm kernel oil • Free fatty acids • Linoleic
Protein	• Whole • Egg, milk, wheat, whey • Isolates • Caseinate salts • Lactalbumin	• Oligopeptides • Dipeptides • Tripeptides • L-Amino acids

Protein Composition

The essential amino acid content of the protein source determines the quality of the protein, and most commercially available enteral feeding formulations contain proteins of high quality. The form of the protein source in enteral formulas will determine the amount of digestion that is required for absorption. Polymeric or intact protein sources require digestion to smaller peptides and free amino acids before absorption. Protein sources, such as meat, milk, eggs, and caseinates, require digestion by hydrochloric acid, specific protein enzymes, and pancreatic proteases. Enteral formulations may also contain protein sources that are partially hydrolyzed to peptides or L-amino acids. As the molecular form of protein is reduced in size, the osmotic load of the enteral formulation is increased. Many commercially available enteral feeding formulations contain combinations of intact and partially hydrolyzed protein sources. Most enteral formulations are gluten-free.

Conditionally Essential Amino Acids

Glutamine and arginine are generally considered nonessential amino acids. However, during periods of high physiologic stress, the need for these nutrients may be increased beyond the body's synthetic ability; consequently, these amino acids are characterized as conditionally essential. Because they are usually present in low amounts in most enteral feeding formulations, formulations targeted for the critically ill may be supplemented with glutamine and/or arginine.

Glutamine serves as a key fuel for rapidly dividing cells, including enterocytes, endothelial cells, lymphocytes, and fibroblasts. The primary site of glutamine production is skeletal muscle. During critical illness, skeletal muscle catabolism provides an increased glutamine supply, but this may not be enough to meet the high rate of glutamine used by cells of the immune system and other cells involved in recovery and repair. Glutamine depletion may develop, particularly during prolonged periods of metabolic stress. Favorable outcomes have been documented in subtypes of critically ill patients when enteral formulations have been supplemented with glutamine.[9] Immune-modulating EN formulas containing glutamine are specifically recommended in patients with traumatic brain injury due to their association with decreased infections.[9] However, high dose glutamine supplementation in critically ill patients with shock and multisystem organ failure should be avoided.[9,33]

Arginine has been added to some immune-modulating enteral formulations in concentrations that range from 4.5 to 14 g/L. Immune-modulating EN formulas containing arginine in combination with fish oil in perioperative patients in the surgical ICU is associated with decreased infections and decreased length of stay.[9] However, arginine supplementation remains controversial, especially in patients with sepsis.[31] Many of arginine's physiologic effects are mediated by its conversion to nitric oxide, which, in turn, modulates immune function, inflammation, and vasodilation. Some of these effects may be potentially harmful in the patient with sepsis, especially when higher arginine intakes are used.[9] Unfortunately, the effects of individual immunonutrients have not been extensively evaluated.

Carbohydrate Composition

The carbohydrate component of enteral feeding formulations usually provides the major source of calories. Polymeric or intact enteral formulations contain starches and numerous types of glucose polymers, which require digestion to monosaccharides prior to intestinal absorption (see Fig. 166-1). As the extent of hydrolysis of carbohydrates increases within an enteral formulation, the osmolality of the formulation increases. Simple sugars, such as glucose and galactose, contribute significantly to the osmolality of enteral formulations. Consequently, polymeric entities, rather than elemental sugars, are preferred. Glucose polymers provide a useful carbohydrate source that is tolerated by most individuals (see Table 166-4). The polymers are large chains that provide minimal osmotic load, yet are absorbed easily in the intestine. The one shortcoming of glucose polymers and oligosaccharides is that they are not as sweet as simple glucose and thus may decrease the palatability of orally consumed products. Finally, almost all commercially available enteral feeding formulations used in adults and older children are lactose-free because disaccharidase production within the gut lumen is reduced during illness and periods of prolonged bowel rest and because lactose intolerance is relatively common in the general adult population.

Fat and Fatty Acid Composition

Fat is an important constituent in the diet because it provides a concentrated calorie source and serves as a carrier for fat-soluble vitamins. Sufficient linoleic acid is required to prevent essential fatty acid deficiency and should approximate at least 1% to 3% of total daily calories. The most common fat sources in enteral feeding formulations are vegetable oils (soy or corn) that are rich in polyunsaturated fatty acids. The fat concentration varies between less than 2% and 45% of total calories. High dietary fat content is associated with delayed gastric emptying. Enteral feeding formulations can also contain fat in the form of MCTs derived from palm kernel or coconut oils. Because MCTs do not contain linoleic acid, enteral formulations that contain MCTs will also have a source of long-chain triglycerides to provide essential fatty acids. Potential advantages of MCTs compared to long-chain triglycerides are that they are more water soluble, undergo rapid hydrolysis, require no pancreatic lipase or bile salts for absorption, and do not require carnitine for transport into the mitochondria, where they are converted to energy. They also do not require chylomicron formation for small bowel enterocyte absorption and are not transported via the lymphatic system.

The source of long-chain fat within some enteral formulations has been modified from omega-6 to omega-3 fatty acids in an effort to modulate the inflammatory response in critically ill patients.[9] The omega-6 fatty acids are high in linoleic acid and are derived from vegetable oil, whereas the omega-3 fatty acids, derived from cold-water fish oils, are high in linolenic acid. Omega-6 fatty acids serve as precursors to certain arachidonic acid-derived cytokines that are potent inflammatory mediators and also decrease cell-mediated immune response; whereas omega-3 fatty acids are precursors for eicosapentanoic acid-derived cytokines which are less inflammatory. It has been proposed that if the dietary proportion of omega-3 fatty acids is increased and omega-6 fatty acids is decreased, less inflammation and immunosuppression may occur during metabolic stress. However, use of enteral formulas containing omega-3 fatty acids in patients with acute respiratory distress syndromes (ARDS) and acute lung injury (ALI) has fallen out of favor, specifically in the medical ICU population with ARDS or ALI. Thus, immune-modulating formulas containing fish oil (in combination with arginine) are reserved for patients requiring EN in the perioperative setting in the surgical ICU.[9]

Fiber Content

Fiber, in both soluble and insoluble forms, is added to several enteral feeding formulations in amounts ranging from 5.9 to 24 g/L. Fiber supplementation is common in clinical practice, primarily because fiber-free enteral formulations are implicated as a contributing factor to both diarrhea and constipation. Soluble fiber stimulates the growth of “healthy” bacteria such as *Bifidobacterium* and *Lactobacillus* species. It undergoes bacterial degradation within the colon to produce short-chain fatty acids, which in turn provide an energy source for colonocytes and trophic effects on the colonic mucosa by promoting sodium and water absorption. Insoluble fiber is undigested and may help decrease GI transit time by increasing fecal weight. Fiber may play an integral role in regulating bowel function with minimal associated risk.[34] Fiber supplementation may be beneficial when long-term EN is required or in patients who experience diarrhea or constipation while receiving a fiber-free enteral formulation. Supplementation with a fermentable soluble fiber is recommended for routine use in all medical and surgical ICU patients who are on a fiber-free EN formula, particularly in the setting of diarrhea, due to possible benefits in maintaining a healthy gut microbiome. Both insoluble and soluble fiber should be avoided in critically ill patients who are at risk for bowel ischemia or severe dysmotility due to potential for bowel obstruction in surgical and trauma ICU patients.[9]

Osmolality and Renal Solute Load

The unit of measure of osmolality is milliosmoles per kilogram (mOsm/kg) or millimoles per kilogram (mmol/kg); iso-osmolar is considered to be approximately 300 mOsm/kg (mmol/kg). Osmolality and renal solute load can affect tolerance to enteral feeding formulations. The osmolality of a given enteral formulation is a function of the size and quantity of ionic and molecular particles, primarily related to the protein, carbohydrate, electrolyte, and mineral content within a given volume. Enteral formulations with greater amounts of partially hydrolyzed or elemental substrates have a higher osmolality than formulations containing polymeric or intact substrates. Therefore, formulations that contain sucrose or glucose, dipeptides and tripeptides, and amino acids are generally hyperosmolar. Increased caloric density also increases the osmolality of an enteral formulation. In general, the osmolality of commercially available enteral feeding formulations ranges from 280 to 875 mOsm/kg (mmol/kg).[32]

Symptoms of gastric retention, diarrhea, abdominal distension, nausea, and vomiting have been attributed to enteral formulations with a high osmolality based on the assumption that higher osmolality draws water into the gut lumen. However, clinical evidence to support this relationship between osmolality and GI tolerance is lacking. The practice of diluting hyperosmolar formulations does not enhance tolerance and is not recommended due to the increased risk of microbial contamination.[17,24] Factors, such as concurrent antibiotic therapy, method of enteral feeding administration, and the formulation’s composition, are likely to play a greater role in GI tolerance than the osmolality.

The renal solute load is determined by the protein, sodium, potassium, and chloride content of the enteral formulation. Formulations that contain a greater solute load increase the obligatory water loss via the kidney. It is estimated that 40 to 60 mL of water is the minimal amount necessary to excrete 1 g of nitrogen. Those receiving high-protein enteral formulations unable to ingest or tolerate supplemental water may be at risk for developing dehydration.

CLASSIFICATION OF ENTERAL FEEDING FORMULATIONS

⑤ Most patients’ nutritional needs can be met using a standard enteral feeding formulation; however, certain disease states or clinical conditions may warrant the use of a specialty feeding formulation. Development of an evidence-based, enteral formulary should focus on clinically significant characteristics of available formulations and avoid duplication. Categorizing enteral feeding formulations according to therapeutic class is necessary for developing a formulary system for adults (Table 166-5).

TABLE 166-5

Adult Enteral Feeding Formulation Classification System

Category	Features	Indications
Standard polymeric	• Isotonic • 1-1.2 kcal/mL (4.2-5 kJ/mL) • NPC:N 125:1-150:1 • May contain fiber	• Designed to meet the needs of the majority of patients • Patients with functional GI tract • Not suitable for oral use
High protein	• NPC:N <125:1 • May contain fiber	• Patients with protein requirements >1.5 g/kg/day, such as trauma patients and those with burns, pressure sores, or wounds • Patients receiving propofol
High caloric density	• 1.5-2 kcal/mL (6.3-8.4 kJ/mL) • Lower electrolyte content per calorie • Hypertonic	Patients requiring fluid and/or electrolyte restriction, such as kidney insufficiency
Elemental	• High proportion of free amino acids • Low in fat	• Patients who require low fat • Use has generally been replaced by peptide-based formulations
Peptide-based	• Contains dipeptides and tripeptides • Contains MCTs	• Indications/benefits not clearly established • Trial may be warranted in patients who do not tolerate intact protein due to malabsorption
Disease-specific		
Kidney	• Caloric dense • Protein content varies • Low electrolyte content	Alternative to high caloric density formulations, but generally more expensive
Liver	Increased branched-chain and decreased aromatic amino acids	Patients with hepatic encephalopathy
Lung	• High fat, low carbohydrate • Antiinflammatory lipid profile and antioxidants	Patients with ARDS and severe ALI
Diabetes mellitus	High fat, low carbohydrate	Alternative to standard, fiber-containing formulation in patients with uncontrolled hyperglycemia

Immune-modulating	Supplemented with glutamine, arginine, nucleotides, and/or omega-3 fatty acids	• Patients undergoing major elective GI surgery, trauma, burns, head and neck cancer, and critically ill patients on mechanical ventilation • Use with caution in patients with sepsis • Select nutrients may be beneficial or harmful in subgroups of critically ill patients
Oral supplement	• Sweetened for taste • Hypertonic	Patients who require supplementation to an oral diet

ALI, acute lung injury; ARDS, acute respiratory distress syndrome; MCT, medium-chain triglyceride; NPC, N, nonprotein calorie-to-nitrogen ratio.

Standard Polymeric

A large number of commercially available enteral feeding formulations fall into the standard polymeric formulation category. These formulations are approximately isotonic (300 mOsm/L), provide 1 to 1.2 kcal/mL (4.2-5 kJ/mL), and are composed of intact nutrients in a nutritionally balanced mix of carbohydrates, fat, and protein. They may contain dietary fiber. The nonprotein calorie-to-nitrogen ratio of these products is approximately 125:1 to 150:1. This ratio is a useful parameter for assessing protein density in relation to calories provided (see Chapter 164). Certain feeding formulations in this category may be promoted as high nitrogen but actually fall within standard protein amounts. To maintain isotonicity, many products within this category are not sweetened, making them unpalatable and generally suited only for tube feeding; however, flavored products are available for oral supplementation. The nutrient requirements of the majority of adults receiving EN can generally be met using feeding formulations in this category.

High Protein

Enteral feeding formulations with a nonprotein calorie-to-nitrogen ratio less than 125:1 can be categorized as high protein. The lower the ratio, the higher the protein density in relation to calories provided. In patients with high protein requirements, it is generally unacceptable to use a feeding formulation with standard protein amounts because the volume necessary to meet protein requirements will result in excessive calorie intake. Patients who may be candidates for a high-protein feeding formulation are critically ill patients and those with pressure sores, surgical wounds, and high output enterocutaneous fistulas. In general, adult patients with estimated protein requirements exceeding 1.5 g/kg/day may benefit from a high-protein formulation. High-protein formulations may also be beneficial in mechanically ventilated patients who are receiving propofol for sedation. The vehicle for propofol is a soybean fat emulsion that contains 1.1 kcal/mL (4.6 kJ/mL). At therapeutic dosages, propofol intake can contribute to caloric intake, and a high protein formulation may be beneficial in allowing for the provision of protein requirements while minimizing overfeeding.

High Caloric Density

High caloric density formulations are concentrated to provide less fluid and electrolyte intake in comparison to a standard polymeric formulation. They provide approximately 1.5 to 2 kcal/mL (6.3-8.4 kJ/mL) and similar calorie and protein intake can be achieved as a standard polymeric formulation, using less volume. High caloric density formulations are often necessary for patients who require fluid and/or electrolyte restriction, such as those with heart, kidney, liver, or respiratory failure. Although specialty enteral formulations targeted for acute kidney injury and chronic kidney disease are available, many patients with kidney failure can be managed using a product in this category.

Elemental/Peptide-Based

Formulations in this category contain protein and/or fat components that are hydrolyzed into smaller, predigested forms. Traditionally, enteral formulations in this category were referred to as elemental and contained a high proportion of protein in the form of free amino acids and a low amount of fat. Many of these formulations have been reformulated to provide a portion of the protein in the form of dipeptides and tripeptides and fewer free amino acids because dipeptides and tripeptides are more readily absorbed than an equivalent intake of free amino acids.[35] These peptide-based formulations may be beneficial in patients with impaired digestion or absorption. Peptide-based formulations are generally higher in fat than the more elemental formulations and use MCTs in varying proportions as the fat source.

Evidence to support the use of elemental or peptide-based formulations is limited, and their routine use is generally not recommended. Patients who do not tolerate standard, intact nutrient formulations as a result of malabsorption or short bowel syndrome might be candidates for a trial of a peptide-based formulation. In addition, elemental or peptide-based products that have higher percentages of MCTs and small amounts of long-chain triglycerides may be beneficial for patients with severe pancreatic insufficiency, such as chronic pancreatitis and cystic fibrosis; severe abnormalities of the intestinal mucosa, such as untreated celiac disease; biliary tract disease, such as biliary atresia or severe cholestasis; or chylothorax or chylous ascites.

Disease-Specific

Enteral feeding formulations have also been designed to meet unique nutrient requirements and manage metabolic abnormalities associated with specific disease states. Specialized enteral feeding formulations are marketed for use in adult patients with kidney and liver failure; lung disease, including ARDS; diabetes mellitus; wound healing; and metabolic stress (see Table 166-5).

Specialized enteral formulations designed to modulate the inflammatory response in adult patients with severe metabolic stress have been referred to as immune-modulating formulations or immunonutrition. These formulations are supplemented with nutrients such as glutamine, arginine, antioxidants, nucleotides, and omega-3 polyunsaturated fatty acids, because of their potential role in regulating immune function. However, nutrition guidelines recommend against the routine use of immune-modulating enteral formulations in the medical ICU population due to the lack of benefit and potential harm. These formulas should be reserved for patients in the surgical ICU and in patients with traumatic brain injury where beneficial effects have been demonstrated.[9,36,37]

Diabetes-specific formulas are lower in carbohydrate and higher in fat and fiber compared to standard formulas.[38] They contain slowly digestible carbohydrates and their primary fat sources are omega-3 fatty acids and monounsaturated fatty acids. The rationale for this combination of ingredients is to slow gastric emptying and improve glycemic control. Use of diabetes-specific formulas in hospitalized patients may lead to an improvement in glycemic control and a decrease in total insulin requirements, but to date the supporting evidence is limited. Therefore, in hospitalized patients with diabetes mellitus or stress-induced hyperglycemia, a standard enteral formula in combination with pharmacologic management of hyperglycemia is appropriate.[38]

Enteral formulas with lower protein, higher amounts of branched-chain amino acids (BCAAs) (leucine, valine, and isoleucine), and lower amounts of aromatic amino acids (AAAs) have been marketed for use in patients with hepatic encephalopathy. However, these formulations may result in under-dosing protein in a population with a high prevalence of malnutrition. Additionally, they do not improve outcomes in patients with hepatic encephalopathy and are therefore not recommended for routine use in this patient population.[32]

Oral Supplements

In general, oral supplements are not intended for tube feeding but are taken by mouth to enhance an oral diet. They are sweetened to improve taste and therefore are hypertonic (~450-700 mOsm/kg [mmol/kg]), but osmolality is rarely a problem in the patient with a functioning GI tract. However, in the tube-fed patient, a sweetened product is unnecessary and may contribute to GI intolerance, particularly diarrhea. Powder supplements that are mixed with milk should be avoided in lactose-intolerant patients. In addition to liquid supplements, puddings, gelatins, bars, and milkshake-like supplements are available.

Modular Products

A module is a powder or liquid form of a single nutrient (eg, protein, carbohydrate, fat, and dietary fiber) that is used to supplement nutrition intake when the diet or commercially available enteral formulation does not fully meet a patient's needs.[32] Alternatively, formulations available in powder or concentrate can be mixed with less water than needed for the standard dilution to deliver more nutrients in less volume. The mixing process required for modular components increases the potential for bacterial contamination and incorrect preparation. Contamination is a particular concern with the use of blenders and reconstitution of powders.[24] Modular products used to supplement tube feedings should not be mixed with the EN formula but administered separately via a feeding tube similar to the process required for medication administration.

Rehydration

Oral rehydration formulations are useful in maintaining hydration or treating dehydration in patients with high GI output (eg, frequent vomiting, diarrhea, ostomy output). Such formulations are available commercially in powder or liquid form or can be extemporaneously compounded. They can be administered orally or given via a feeding tube. The glucose content of oral rehydration solutions is essential to the absorption of sodium, because it stimulates active transport systems, which, in turn, stimulate passive glucose-coupled sodium and water uptake for rehydration. Therefore, oral or enteral administration of rehydration solutions may decrease fecal water loss and generate a positive fluid and electrolyte balance.[39]

FORMULARY AND DELIVERY SYSTEM CONSIDERATIONS

For an institution's enteral formulary, generally no more than one product per category is necessary, and it may be possible to omit certain categories based on the specific patient population cared for within a given institution. Additional selection criteria include container size and type, liquid or powder form, shelf life, ease of use, and cost.

Most enteral products are available as ready-to-use, prepackaged liquids, but a few are available in the powdered state and require reconstitution prior to use. Advantages of ready-to-use liquid formulations are convenience and reduced susceptibility to microbiologic contamination. One disadvantage is that more storage space may be required. The ease or convenience of a ready-to-use liquid is especially important for self-care patients, those with disabilities, and those who have difficulty reading or following printed instructions. Ready-to-use liquid enteral formulations are generally available in ready-to-hang rigid plastic containers or bags (*closed systems*), cans, or bottles. Bolus administration of EN is usually achieved using formulas available in cans or bottles. However, when formula from a can/bottle is used for continuous or cyclic administration, it must first be poured into a feeding bag and attached to an administration set to allow for administration via a pump. This "open system" has a higher risk of microbial contamination than the ready-to-hang containers. The use of a powder formula is also considered an open delivery system.

Contamination of enteral feeding formulations is a potential cause of diarrhea.[7,24] Contamination is caused by a lack of attention to proper handling techniques, inadequate cleaning and disinfection of preparation equipment, and the use of nonsterile or contaminated tube-feeding additives. Unlike liquid formulations, powdered products are not guaranteed by the manufacturer to be sterile because it is not possible to sterilize the powder without destruction of some of its components. Closed-system containers supply a ready-to-hang, prefilled, sterile supply of formula in volumes of 1 to 1.5 L. Most but not all enteral formulations intended for use in adults are available in the closed-administration system. The closed-administration system also offers the advantage of not requiring refrigeration and allowing hang times of 24 to 48 hours, whereas the conventional open-delivery system necessitates hang times of generally 4 to 8 hours.[24]

New enteral connectors are being integrated into the EN marketplace to prevent enteral misconnections and improve patient safety. An enteral misconnection occurs when a component of the enteral feeding system is inadvertently connected to a non-enteral site, such as a tracheostomy tube, peritoneal dialysis catheter, or other medical device or intravenous (IV) tubing. Misconnections are commonly attributed to the use of universal connectors that allow for misconnections between incompatible systems. Due to potential serious patient harm, including death, an international standard (ISO 80369) has been developed to guide the redesign of all small-bore connectors and the new enteral connectors, referred to as the ENFit^{TM} system.[40] The ENFit^{TM} connector provides a unique connection that is not compatible with any other device and has been specifically designed for all nutrition sources, enteral administration sets, enteral syringes, and all feeding tubes.[40] Thus, filling and administration instructions for syringes used to deliver medications via feeding tubes should differ from oral syringes with the implementation of the ENFit^{TM} system. Information about these processes and other resources is available at the Global Enteral Device Supplier Association (GEDSA) website (www.stayconnected.org).[41]

COMPLICATIONS AND MONITORING

The majority of complications associated with EN are metabolic, GI, or mechanical. The early detection and management of potential complications is necessary to allow for the safe and successful use of EN. In addition, measures to avoid complications should be incorporated into the management of all patients receiving EN (Table 166-6).

TABLE 166-6

Suggested Monitoring for Adult Patients on Enteral Nutrition

Parameter	During Initiation of EN Therapy	During Stable EN Therapy
Vital signs	Every 4-6 hours	As needed with suspected change (ie, fever)
Clinical assessment		
Weight	Daily	Weekly
Total intake/output	Daily	As needed with suspected change in intake/output
Tube-feeding intake	Daily	Daily
Enterostomy tube site assessment	Daily	Daily
GI tolerance		
Stool frequency/volume	Daily	Daily
Abdomen assessment	Daily	Daily
Nausea or vomiting	Daily	Daily
Tube placement	Prior to starting, then ongoing	Ongoing
Laboratory		
Electrolytes, blood urea nitrogen/serum creatinine, glucose	Daily until stable, then 2-3 times/week	Every 1-3 months
Calcium, magnesium, phosphorus	Daily until stable, then 2-3 times/week	Every 1-3 months
Liver function tests	Weekly	Every 1-3 months
Trace elements, vitamins	If deficiency/toxicity suspected	If deficiency/toxicity suspected

EN, enteral nutrition.

Metabolic Complications

Metabolic complications associated with EN are similar to those associated with PN, but the incidence tends to be lower.[17] Critically ill patients, especially those with underlying organ dysfunction, are at the risk of developing complications related to hydration and electrolyte imbalance and altered glucose control. Patients who present with a history of minimal dietary intake for an extended period of time and have experienced significant weight loss are at risk of developing refeeding syndrome, which can be evidenced by hypophosphatemia, hypokalemia, hypomagnesemia, thiamine deficiency, and sodium retention.[42] The frequency of clinical and laboratory assessment to monitor hydration, electrolytes, organ function, and glucose adequately for a patient who is critically ill or at risk of developing refeeding syndrome is greater than for a stable hospitalized patient or patients residing in rehabilitation units or at home (see Table 166-6). Patients receiving long-term EN at home may require laboratory monitoring only every 2 to 3 months, depending on their clinical status. It is also important to evaluate the actual water and micronutrient content provided by the enteral formulation, especially in critically ill patients. Supplemental fluid, electrolytes, and minerals may be required in some patients. Conversely, for patients who have fluid retention or elevated serum electrolytes, the enteral formulation may need to be changed to one that is more concentrated or provides less of a particular nutrient, if available.

Gastrointestinal Complications

⑥ The GI complications associated with tube feeding include nausea, vomiting, abdominal distension, cramping, aspiration, diarrhea, and constipation. GRV refers to the volume of contents in the stomach and is measured by using a syringe and aspirating from a large-bore NG or gastrostomy tube. Historically, GRV has been used to identify patients at risk of vomiting, aspiration, and/or ventilator-associated pneumonia. However, when GRV alone is used to assess tolerance to EN, it can lead to unnecessary holding of EN and prevent patients from meeting their EN goal.[43] Further, introducing stomach acid into feeding tubes may contribute to clogging. Current guidelines recommend against the use of GRV as part of routine monitoring for ICU patients receiving EN.[9,44] However, some argue that GRV monitoring remains a useful tool in patients at high risk for EN intolerance, and it continues to be used in some practice settings.[44] For ICUs that continue to utilize GRV, avoid holding EN in response to any GRV less than 500 mL in the absence of other symptoms suggesting intolerance (eg, nausea, abdominal pain, distension).[9]

If symptoms of intolerance are present, and GRVs are greater than 500 mL, a decrease in the tube feeding rate or discontinuation may be warranted. Unless GRVs are excessive (greater than 500 mL in adults), they are generally reinstilled through the tube to minimize nutrient, fluid, and electrolyte losses. In patients at high risk for aspiration, clinicians should implement other measures to reduce aspiration risk, including elevating the head of the patient's bed to a 30° to 45° angle, advancement of the feeding tube into the small bowel, and initiation of a prokinetic agent such as metoclopramide or erythromycin.[17,24] Other potential interventions include minimizing the use of narcotics, sedatives, or other agents that may slow gastric emptying and correcting underlying fluid and electrolyte imbalances that can impair GI motility.[24] Aspiration pneumonia is considered the most serious complication associated with tube feeding. Although aspiration is a fairly common event for critically ill patients receiving tube feeding, progression to aspiration pneumonia is difficult to predict. Risk factors for aspiration include a previous aspiration episode, decreased consciousness, neuromuscular disease, structural airway or GI tract abnormalities, endotracheal intubation, vomiting, persistently high GRVs, and prolonged supine positioning.[44] Historically, blue food coloring had been added to enteral formulations in an attempt to detect aspiration. However, because of its low sensitivity for detection and association with several serious adverse medication reactions, including death associated with mitochondrial toxicity, the addition of blue food dye to enteral formulations is not advised. There are no reliable methods available to detect aspiration in enterally fed patients.[9]

Diarrhea is the most common GI complication in patients receiving EN, but the actual incidence is unclear due to the lack of a standard definition and the large number of contributing factors.[7,17] When monitoring for diarrhea, stool frequency, consistency, and volume should be evaluated, and previous bowel habits should be considered. Diarrhea has been defined as more than three liquid stools daily or a stool volume of more than 250 to 500 mL/day for at least two consecutive days.[17] Therefore, the intermittent occurrence of one or two loose stools does not constitute diarrhea or require intervention.

⑦ Diarrhea in patients receiving tube feeding may be caused by a number of factors, and the management should be directed at identifying and correcting the most likely cause(s).[17] Tube feeding-related factors that may contribute to diarrhea include too rapid delivery or advancement of formula, intolerance to the formula composition, administration of large volumes of feeding into the small bowel, and formula contamination. Thus, measures to prevent or manage diarrhea-related directly to the tube feeding should address these potential causes.[17] If diarrhea occurs when using a fiber-free formulation, a fiber-containing formulation or supplement may be considered in hemodynamically stable patients. If using a high-fat formulation, it may be beneficial to switch to a formulation lower in fat or having a higher proportion of the fat supplied as MCTs; although, a high MCT concentration has also been associated with diarrhea. Finally, it is important to assess the risk of bacterial contamination of the formula and take steps to minimize any potential risk factors. If infectious etiologies have been excluded, severe diarrhea may require pharmacologic treatment with loperamide, diphenoxylate/atropine, or opioids (see Chapter 54).

Medication therapy, particularly the use of broad-spectrum antibiotics, is a common cause of diarrhea that is unrelated to tube feeding. Sorbitol, used as a sweetening agent in many liquid formulations to enhance palatability, is an osmotic laxative that can cause diarrhea. In addition, many medications available in a liquid form are hyperosmolar, which may contribute to diarrhea, especially when these medications are not diluted properly before administration. Because many patients receiving tube feeding also receive medications in a liquid form, all medications should be evaluated for their potential contribution. Malabsorption, secondary to the underlying disease state or condition, may also cause diarrhea. Infectious causes, such as antibiotic-induced bacterial overgrowth by *Clostridioides difficile* or other intestinal flora, need to be considered when diarrhea develops. Certain probiotic strains may have a role in the prevention and treatment of infectious and antibiotic-associated diarrhea.[45] However, the value of adding probiotics to patients on EN in the ICU setting is unclear. The makeup of intestinal flora becomes disrupted in response to antimicrobial treatment and stress response of ICU patients. The use of probiotics has been associated with the reduction of ventilator-associated pneumonia, antibiotic-associated diarrhea, and overall infections in critically ill patients.[5,9] However, the existing evidence is limited. Further, the use of probiotics concomitantly with fiber and jejunal feeding in patients with severe acute pancreatitis increases risk of mortality. Therefore, the use of studied probiotic strains should be considered only for select ICU patient populations such as trauma, pancreatectomy, and liver transplantation.[9]

Mechanical Complications

Mechanical complications of EN are those associated with the feeding tube, including tube occlusion or malposition, and inadvertent nasopulmonary intubation. Feeding tube occlusion usually results from improper medication administration and/or flushing. Kinking of the tube may also cause occlusion. Adult feeding tubes should be flushed with at least 15 to 30 mL of water before and after administering any medication. If more than one medication is scheduled for a given time, each should be administered separately, and the tube should be flushed with 5 to 15 mL of water between medications.[24,46] The frequency of flushing should be at least every 8 hours during continuous feeding and before and after each intermittent feeding. If tube occlusion occurs, the tube should be irrigated with warm water. Other fluids such as carbonated beverages and cranberry juice have been used to irrigate occluded tubes but are likely not any more effective than warm water. Because the acid in these liquids may actually precipitate with protein in the enteral formula and lead to new or worsening of occlusions, this practice should be avoided.[24] Pancreatic enzymes mixed with sodium bicarbonate may be used to reestablish patency in this situation.[46] Declogging devices that are specifically designed to unclog feeding tubes are available. They have been designed to either mechanically break through or remove the occlusion or provide an applicator and syringe prefilled with pancreatic enzymes and various powders targeted to restore patency.[7,46]

Inadvertent nasoenteric tube removal or displacement has been reported in approximately 40% of patients receiving EN.[47] An agitated or confused patient may pull at the feeding tube and cause its removal or malposition. Measures to decrease agitation and confusion should be attempted. Securing the tube with tape may be helpful, as well as marking the tube with permanent ink at the exit site to assess for position change. A nasal bridle that uses a magnetic retrieval system has proven to be a simple and effective method for securing nasoenteric feeding tubes and preventing accidental removal.[48]

When a feeding tube is inserted nasally or orally, there is a risk that the tube may inadvertently enter the tracheobronchial tree. The risk may be higher in patients who have an impaired cough or gag reflex and when a stylet is used for tube insertion. Proper positioning of the tube should always be confirmed by radiography prior to feeding initiation and routinely reassessed to avoid inadvertent administration of enteral formula into the lung.[24]

Other Complications

Infectious complications of feeding tube placement include sinusitis (with nasoenteric placement), exit site-related infections (eg, cellulitis, subcutaneous abscess, necrotizing fasciitis), and intraabdominal infections (eg, peritonitis, abscess). Leaking and bleeding around the exit site can also occur.[12] Formation of excessive granulation tissue around the exit site is often the cause of leaking and bleeding and can be managed by applying silver nitrate and topical corticosteroids.[49]

NUTRITION CARE PLAN

A nutrition care plan that incorporates nutrition assessment and therapy goals should be developed for all patients who require EN (see Chapter 164). Desired outcomes of EN are to promote an adequate nutritional state while minimizing any associated metabolic complications. The EN goals are individualized and based on meeting estimated fluid, calorie, protein, and micronutrient requirements. The desired end point should be included in the care plan. The end point may be resolution of a disease or condition that impairs ability to eat, such as in a critically ill patient who is expected to transition back to an oral diet. EN may be considered a lifelong therapy for those with a permanent impairment that restricts or limits eating, such as gastroparesis.

Assessing the outcome of EN requires monitoring objective measures of body composition, protein and energy balance, and muscle function and wound healing. In addition to optimizing nutrition, the goal of EN is to reduce disease-related morbidity and mortality. Measures of disease-related morbidity include length of hospital stay, infectious complications, and the patient's functional status and sense of well-being. A target weight should be established for each patient and energy content from the EN regimen adjusted as needed to safely achieve or maintain the target weight. Adult patients should generally gain or lose no more than 1 to 2 pounds (~0.45-0.9 kg) per week. EN may be used to supplement an oral diet when oral intake is inadequate and should be modified as needed based on changes in tolerance.

MEDICATION DELIVERY VIA FEEDING TUBE

Using enteral feeding tubes to deliver medications is a common practice and offers an alternative for patients unable to take medications by the oral route. However, in addition to tube occlusion, effects on medication bioavailability and other potential interactions need to be considered when using this route. Medications have been given as a concomitant bolus administration via the feeding tube or admixed with the enteral feeding formulation.

Concomitant Medication Administration

⑧ Concomitant administration of medications with enteral feedings can be extremely complicated and potentially deleterious. Depending on the indication for enteral nutrition (eg, inadequate oral intake), oral administration may still be the most appropriate route for medication administration.[24] Therefore, if it is feasible and appropriate, oral medications should be continued to be delivered orally whenever possible. If medication must be delivered through a feeding tube, then larger bore feeding tubes (eg, nasogastric or gastrostomy tubes) are preferred over small bore tubes. Delivering medications directly into the stomach allows for the normal process of drug dissolution. Medication delivery directly into the small bowel however may result in alterations in drug dissolution because the stomach is bypassed. In addition, therapeutic effects designed to occur within the stomach, such as with antacids and sucralfate, may not be achieved. Because many medications are best absorbed in the fasting state, care should be taken to ensure proper timing of drug administration relative to EN administration when clinically appropriate. Patients on bolus gastric feeding must receive these medications appropriately spaced between feedings, and patients on continuous feeding may require feeding interruptions for drug administration.

Selecting the proper medication dosage form for coadministration with the tube feeding is another important consideration. If crushing a given solid dosage form results in changes to medication absorption, then it should be avoided. Medications in sublingual form, sustained-release capsules or tablets, and enteric-coated tablets should not be crushed and therefore should not be administered via enteral feeding tubes.[24,46] Solid dosage forms that are appropriate to crush should be prepared as a fine powder and mixed with 15 to 30 mL of purified water or other appropriate solvents before administering through the tube. In addition, many capsules may be opened and the contents administered in the same manner. Pellets contained inside microencapsulated dosage forms should generally not be crushed. It may be acceptable to administer intact pellets through larger bore feeding tubes, provided that the pellets are small enough and drug absorption is not compromised.[50] To avoid the need to crush a solid dosage form, liquid dosage forms are commonly preferred for administration through feeding tubes. However, the risk of GI intolerance should be considered because of the hyperosmolality of many liquid formulations and possible sorbitol content.[46,51] Although the use of a liquid dosage preparation may be more convenient than a solid dosage form, it may not be the best choice if GI intolerance is an issue.

Admixture of Medications with Enteral Feeding

Mixing liquid medications with certain enteral feeding formulations is associated with several types of physical incompatibilities, including granulation, gel formation, separation, and precipitation.[46,51] Not only can these physical incompatibilities inhibit drug absorption, but gel formation may clog small-bore feeding tubes. Physical incompatibility with medications is more common in formulations that contain intact protein than in those with hydrolyzed protein. Also, medication and enteral formula incompatibilities are more common with the use of acidic pharmaceutical syrups. The most prudent recommendation is to avoid the routine admixture whenever possible, especially for nonaqueous preparations and syrups. In the clinical setting, exceptions do exist, such as adding sodium or magnesium to enteral formulas to assist in maintaining or repleting electrolytes. However, this practice has fallen out of favor, and a closed EN delivery system should be used whenever possible to minimize the risk of contamination.[24]

Drug-Nutrient Interactions

⑨ The most significant drug-nutrient interactions that can occur during continuous enteral feeding are those in which the drug's bioavailability is reduced, and the desired pharmacologic effect is not achieved (Table 166-7).[52] One of the well-documented interactions is between phenytoin and enteral feeding. Phenytoin serum concentrations may decrease by 50% to 75% when phenytoin is given concomitantly with EN, possibly as a result of the binding of phenytoin to calcium caseinates or protein hydrolysates in the enteral formulation. Management options include holding EN for one to two hours before and after drug administration in addition to flushing the tube with water before and after medication delivery. The dosing of phenytoin should be divided into two doses per day rather than three divided doses to minimize interruption of EN. If EN cannot be held around the administration of phenytoin suspension per tube, then patients will typically require higher than normal phenytoin doses.[46] The patient's clinical response and phenytoin serum concentrations should be monitored to assure that the desired therapeutic effects are achieved.

TABLE 166-7

Select Medications with Special Considerations for Enteral Feeding Tube Administration

Drug	Interaction	Comments
Phenytoin	• Reduced bioavailability in the presence of tube feedings • Possible phenytoin binding to calcium caseinates or protein hydrolysates in enteral feeding	• To minimize interaction, holding tube feedings 1-2 hours before and after phenytoin has been suggested • Adjust tube-feeding rate to account for time held for phenytoin administration • Monitor phenytoin serum concentration and clinical response closely • Consider switching to IV phenytoin or an alternative treatment option if unable to reach therapeutic serum concentration
• Fluoroquinolones • Tetracyclines	Potential for reduced bioavailability because of complexation of drug with divalent and trivalent cations found in enteral feeding	• Consider holding tube feeding 1 hour before and after administration • Avoid jejunal administration of ciprofloxacin • Monitor clinical response
Warfarin	Decreased absorption of warfarin because of enteral feeding; therapeutic effect antagonized by vitamin K in enteral formulations	• Adjust warfarin dose based on INR • Anticipate need to increase warfarin dose when enteral feedings are started and decrease dose when enteral feedings are stopped • Consider holding tube feeding 1 hour before and after administration
• Omeprazole • Lansoprazole	Administration via feeding tube complicated by acid-labile medication within delayed-release, base-labile granules	• Granules become sticky when moistened with water and may occlude small-bore tubes • Granules should be mixed with acidic liquid when given via a gastric feeding tube • An oral liquid suspension can be extemporaneously prepared for administration via a feeding tube

INR, International normalized ratio

Decreased bioavailability of certain antibiotics, particularly quinolones, has been documented when coadministered with enteral feeding due to complexation with multivalent cations such as calcium, magnesium, and iron contained in the feeding.[46,50] Although the practice of holding tube feeding for 30 minutes before and 30 minutes after quinolone administration has been recommended, it does not improve drug absorption. Another option is to increase the quinolone dose when given concurrently with EN. Oral ciprofloxacin is absorbed primarily in the duodenum and early jejunum. Ciprofloxacin bioavailability is significantly decreased when given via a jejunostomy tube due to bypassing the site of absorption, so this practice should be avoided.[46]

Warfarin resistance has been documented during enteral feeding, possibly as a consequence of decreased absorption, binding to protein in EN, or the antagonist effects of vitamin K in the feeding formulation. Before 1980, it was thought that the content of vitamin K (up to 1,330 μg/1,000 kcal [or 317 μg/1,000 kJ] of enteral feeding formula) was contributing to the pharmacologic interaction with warfarin. Subsequently, the vitamin K content within formulas intended for use in adults was reduced to less than 200 μg/1,000 kcal (or 48 μg/1,000 kJ). However, warfarin resistance continues to be reported in patients on EN. Holding EN for one hour before and after warfarin administration along with close monitoring of the International Normalized Ratio is warranted to ensure therapeutic drug concentrations are maintained.[53] Conversely, when EN is discontinued, a reduction in warfarin dosage may be required.

Decreased absorption of levothyroxine has been described in patients receiving continuous EN.[50,54] This is thought to be due to the binding of the medication to the tube feeding formula and/or the binding of thyroid hormones to enteral nutrition during enterohepatic recirculation. Several recommendations have been described, including holding tube feedings for one hour before and after medication administration and increasing the dose of levothyroxine while continuous tube feedings are required. Thyroid function tests should be monitored closely (eg, every 7 days) during this time.[54]

CONCLUSION

Identifying appropriate candidates for EN and designing a personalized EN regimen and monitoring plan is a complex process that is often under-appreciated. The successful use of EN can minimize the need for PN in patients unable to meet nutrient requirements with an oral diet. Ultimately, no disease process can improve with prolonged starvation and malnutrition. The American Society for Parenteral and Enteral Nutrition (ASPEN) has identified safety issues related to the administration and management of EN and created practice recommendations based on evidence-based research and expert opinion. These guidelines address the provision and assessment of nutrition support therapy, including EN for adult critically ill patients.[9,24] A multidisciplinary team approach, either as a formal nutrition support service or as a team of caregivers within the practice setting, is recommended to optimize patient outcomes.

SELF-ASSESSMENT QUESTIONS

1. Enteral administration sets with universal connectors increase the risk of:

   A. Feeding tube occlusions

   B. Tube feeding intolerance

   C. Malpositioning of the feeding tube

   D. Enteral misconnections

2. Which of the following strategies has been recommended to minimize the risk of aspiration in patients receiving enteral nutrition?

   A. Keep the head of the bed elevated to a 30- to 45-degree angle

   B. Add blue food dye to the enteral formula

   C. Change from continuous to bolus administration

   D. Change from standard polymeric to high caloric density formula

3. The end-product of bacterial degradation of fiber within the colon is:

   A. Medium-chain triglycerides

   B. Long-chain triglycerides

   C. Short-chain fatty acids

   D. Omega-3 fatty acids

4. In a patient with gastroparesis who has failed nasogastric feeding and will require long-term enteral nutrition and gastric decompression in the home setting, the *preferred* access choice is:

   A. Nasojejunal

   B. Gastrostomy

   C. Jejunostomy

   D. Gastro-jejunostomy

5. An advantage of the bolus method of enteral nutrition administration compared to the continuous method is that it:

   A. Requires less equipment

   B. Can be used for rapid delivery into the jejunum

   C. Is better tolerated

   D. Can be used with all types of feeding tubes

6. Enteral nutrition should be *avoided* in which of the following patients?

    A. A patient receiving cancer chemotherapy

    B. A patient with >50% total body surface area burn

    C. A patient with bowel ischemia

    D. A patient with acute pancreatitis

7. Which of the following techniques is *most appropriate* for medication administration via a nasogastric feeding tube?

    A. Routinely hold the feeding for one hour before and after administering medications.

    B. Flush the tube with 15 to 30 mL of water before and after administration of each medication

    C. Pellets contained within a microencapsulated dosage form should generally be crushed prior to administration.

    D. If more than one medication is scheduled for the same time, they should be mixed prior to administration.

8. A patient who has a stable INR between 2 and 3 while receiving warfarin with continuous tube feeding is transitioned off of tube feeding to an oral diet. Which of the following INR values is most likely to result after this change?

    A. 1

    B. 1.5

    C. 2.5

    D. 4.5

9. Which of the following is a result of gut barrier dysfunction?

    A. Secretion of immunoglobulins by gut-associated lymphoid tissue (GALT)

    B. Small bowel peristalsis

    C. Bacterial translocation

    D. Secretion of hydrochloric acid by the stomach

10. In an older adult with a history of massive stroke and a hemicolectomy, which of the following is a potential *advantage* of enteral nutrition via a jejunostomy compared with a gastrostomy?

    A. Decreased risk of aspiration

    B. Decreased diarrhea

    C. Decreased infection risk

    D. Decreased cost associated with placement

11. When initiating enteral nutrition in a hospitalized patient with a jejunostomy, which of the following methods is *preferred*?

    A. Continuous infusion at a rate of 120 mL/hr

    B. Continuous infusion at a rate of 20 mL/hr

C. Bolus administration at a dose of 480 mL every 4 hours

D. Intermittent administration at a dose of 480 mL every 4 hours

12. Which of the following is an *advantage* of enteral nutrition compared to parenteral nutrition?

A. Lower risk of aspiration

B. Decreased incidence of gastrointestinal intolerance

C. Lower risk of cholestasis

D. Fewer administration interruptions

13. Which of the following enteral formulas is *most likely* to contribute to the development of diarrhea?

A. Use of a fiber-containing formula

B. Use of a peptide-based formula

C. Use of an MCT-containing, low fat formula

D. Use of a powder formula that requires reconstitution

14. In an adult patient receiving enteral nutrition who experiences a gastric residual volume of 150 mL, which of the following interventions is *preferred*?

A. Hold the feeding

B. Decrease the administration rate

C. Dilute the formulation and continue the same rate

D. No intervention required

15. When should enteral nutrition be initiated in most adult critically ill patients who are mechanically ventilated?

A. Within 6 hours of arrival to the intensive care unit

B. Within 24 to 48 hours of arrival to the intensive care unit

C. After 5 to 7 days of admission to the hospital

D. It depends on the patient's underlying nutritional status

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** Enteral misconnections are commonly attributed to the use of universal connectors that allow for inappropriate connections between different delivery systems such as enteral tubing and intravenous tubing. Answers A, B, and C refer to different types of feeding tube complications unrelated to misconnections. See the "Formulary and Delivery System Considerations" section.

2. **A.** One strategy to lower aspiration risk is to elevate the patient's head of the bed to a 30° to 45° angle. Addition of blue food dye to enteral feeding is not recommended due to reports of mitochondrial toxicity from this practice (B is incorrect). Answer C is incorrect because bolus feeding would be more likely to increase aspiration risk. Answer D is incorrect because these are strategies that may affect tolerance to a tube feeding formula is not a standard strategy to reduce aspiration risk. See the"Gastrointestinal Complications" section.

3. **C.** The end-product of bacterial degradation of fiber within the colon is short-chain fatty acids. These fatty acids serve the important role of

providing energy and nourishment for the colonic mucosa. See the “Digestion and Absorption” section.

4. **D.** The enteral tube option that can provide both a route for enteral nutrition and a route for gastric decompression is a gastrojejunostomy tube. This type of tube has two lumens – one that ends in the stomach (for removal of gas and fluid/decompression) and one that ends in the jejunum (for feeding). A, B, and C are incorrect because none of these options provide both a route of decompression and feeding. See the “Long-Term Access” section.

5. **A.** Bolus administration of enteral nutrition (EN) requires less equipment compared to other methods of administration such as continuous or cyclic enteral nutrition, which require a pump. Options B is incorrect because bolus feeding is never appropriate for delivery into the jejunum. C is incorrect because bolus feeds are not typically better tolerated. D is incorrect because bolus feeds are only an option for gastric feeding tubes (not any feeding tube that delivers EN into the small bowel). See the “Administration Methods” section.

6. **C.** Bowel ischemia is considered a contraindication to delivery of enteral nutrition. Answers A, B, and D are incorrect because none of these options are contraindications to EN. See the “Indications for Enteral Nutrition” section.

7. **B.** The feeding tube should be flushed with 15 to 30 mL of water before and after administration of each separate medication. The feeding tube should be flushed with 15 to 30 mL of water before and after administration of each separate medication. Holding EN for 1 hour before and after medication administration is only necessary for medications with known interactions with EN (A is incorrect). Pellets or any extended release dosage forms should not be crushed (C is incorrect). Each medication should be delivered separately and never mixed prior to administration (D is incorrect). See the “Mechanical Complications” and “Medication Delivery via Feeding Tube” sections.

8. **D.** An INR of 4.5 reflects an increase in INR, which corresponds to the transition from continuous EN to an oral diet. Warfarin resistance has been documented during administration with enteral feeding. Therefore, when EN is discontinued, one can expect an increased response to a patient’s warfarin dose. Answers A, B, and C are incorrect because these values reflect unchanged or lower INR values. See the “Drug–Nutrient Interactions” section.

9. **C.** Bacterial translocation can occur due to dysfunction of the gut barrier. See the “Gut Host Defense Mechanism” section.

10. **A.** Feeding into the jejunum (eg, small bowel feeding) is a good option for patients at increased aspiration risk such as those with a history of stroke. Answers B, C, and D are incorrect because these options do not correctly describe benefits of jejunal feeding. See the “Enteral Access” section.

11. **B.** Small bowel feeding in hospitalized patients should be initiated at lower rates such as 10 to 30 mL/hr with further advancement to goal as tolerated. Higher volumes associated with bolus or intermittent feedings are not recommended for small bowel feeding (C and D are incorrect). Option A is incorrect because it is too high for an initial rate when EN is first started. See the “Initiation and Advancement Protocol” section.

12. **C.** Enteral nutrition is associated with a lower risk of cholestasis compared to parenteral nutrition because EN stimulates bile flow through the biliary tract. Patients requiring bowel rest and parenteral nutrition are at increased risk for cholestasis due to the lack of bile flow stimulation. Options A, B, and D are incorrect because these are all complications that are more common with EN than parenteral nutrition. See the “Enteral Versus Parenteral Nutrition” section

13. **D.** The process of reconstituting enteral nutrition introduces a higher risk of contamination which is a potential cause of diarrhea. Options A, B, and C are incorrect because these describe alternative EN formulas that may improve diarrhea attributed to EN. See the“Formulary and Delivery System Considerations” section.

14. **D.** Routine monitoring of gastric residual volume (GRV) is not recommended because it can lead to unnecessary hold of EN and potentially even increase the risk for clogging of the feeding tube. However, if GRV is used as a monitoring tool, avoid holding EN in response to any GRV less than 500 mL unless other symptoms of intolerance are present. Therefore, no intervention is required for a single GRV of 150 mL in the absence of other symptoms (D is correct; A, B, C are incorrect). See the“Gastrointestinal Complications” section.

15. **B.** Guidelines for critically ill adults recommend the initiation of enteral nutrition within 24 to 48 hours of arrival to the intensive care unit for most adults. While subsets of patients may benefit for early EN, such as within 6 hours, most ICU patients are still undergoing resuscitation during this time and it may not be feasible or advisable to initiate EN at this point (A is incorrect). EN initiation after 5 to 7 days is appropriate for well-nourished, non-critically ill patients in the hospital but this is too long to go without EN for critically ill adults (C is incorrect). Current guidelines refer to nutrition status

and nutrition risk as important factors for considering how quickly a nutrition regimen is advanced to goal, but this does not play into the recommendation on when EN should be initiated in the ICU (D is incorrect). See the "Timing of Initiation" section.

Chapter 167: Obesity

Amy H. Sheehan; Judy T. Chen; Jack A. Yanovski

KEY CONCEPTS

KEY CONCEPTS

① Two clinical measures of excess body fat, regardless of sex, are the body mass index (BMI) and the waist circumference (WC). BMI and WC provide a better assessment of total body fat than weight alone and are independent predictors of obesity-related disease risk.

② Excessive central adiposity increases risk for development of type 2 diabetes mellitus, hypertension, and dyslipidemia.

③ Weight loss goals should be determined based on severity of obesity-related complications. Treatment selection and intensity of obesity intervention varies depending on the phase of prevention and treatment in which the patient resides. Sustained, large weight losses (ie, after bariatric surgery) are associated with a lower risk of cardiovascular events and death and with long-term improvements in many of the complications associated with obesity.

④ Clinicians should consider the weight-altering effects of medications used to treat comorbid conditions (eg, antidepressants, antipsychotics, antiepileptics, and antidiabetics) and select medications that promote weight loss or are weight-neutral.

⑤ Bariatric surgery is reserved for adolescents with extreme obesity (BMI more than or equal 35 kg/m^2 or more than or equal 120% of the 95th percentile for age, whichever is lower, with a severe comorbidity, or in youth with BMI more than or equal 40 kg/m^2 or more than or equal 140% of the 95th percentile for BMI, whichever is lower, with any obesity-related comorbidity) and adults with extreme obesity (BMI more than or equal 40 kg/m^2 or BMI more than or equal to 35 kg/m^2 with a major comorbidity).

⑥ Pharmacotherapy may be considered an adjunctive treatment in adolescents age 12 years and older with BMI corresponding to 30 kg/m^2 or greater for adults (more than or equal to the 95th percentile for age) and adults with a BMI more than or equal to 30 kg/m^2 or BMI of 27 to 30 kg/m^2 with a comorbidity if comprehensive lifestyle modifications (eg, diet, exercise, behavioral modification) fail to achieve or sustain weight loss.

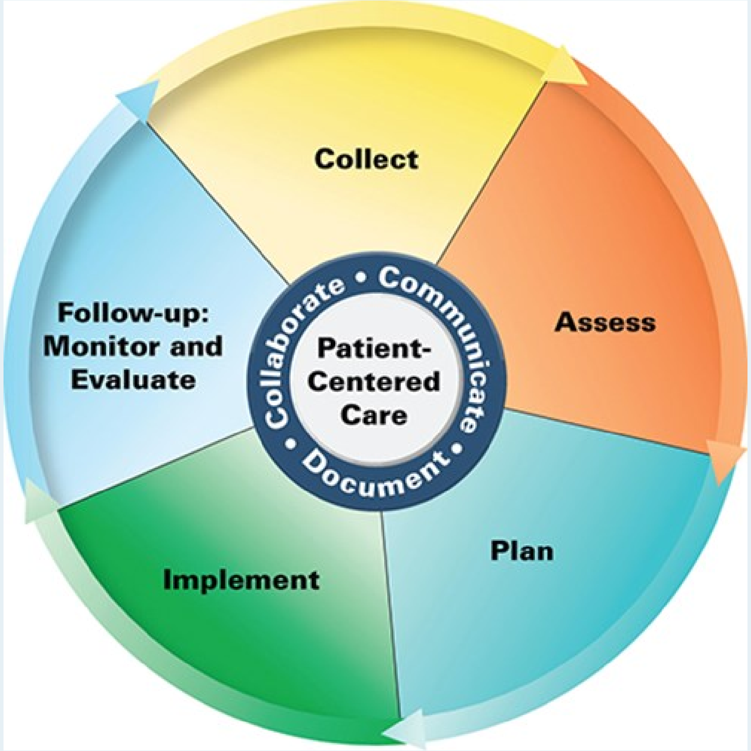
⑦ Weight regain occurs with a high probability when pharmacotherapy for obesity is discontinued.

⑧ Pharmacotherapy should be discontinued if weight loss of at least 5% is not achieved after 12 weeks of maximum-dose therapy with phentermine-topiramate, bupropion-naltrexone, or setmelanotide because significant weight loss is unlikely to be achieved despite continued therapy. Liraglutide should be discontinued if weight loss of at least 4% is not achieved after 16 weeks of therapy. There is no recommendation for early discontinuation of semaglutide.

⑨ The Food and Drug Administration (FDA) does not regulate labeling of herbal and food supplement diet agents, and content is not guaranteed.

PATIENT CARE PROCESS

Patient Care Process for Management of Obesity



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient characteristics (eg, age, race, sex)
- Patient history (past medical, family, social—dietary habits, tobacco use)
- Obesity-related conditions (see Table 167-1)
- Current medications including prescription, non-prescription, and herbal product use
- Weight loss history and prior attempts to lose weight
- Objective data
    - Height, weight, BMI, waist circumference, and blood pressure
    - Labs (eg, fasting glucose, hemoglobin A1c, lipid panel)

Assess

- Causes of secondary obesity (eg, insulinoma, Cushing syndrome)
- Current medications that may contribute to weight gain
- Presence of obesity-related comorbidities (eg, hypertension, dyslipidemia, coronary artery disease, type 2 diabetes mellitus, sleep apnea, increased waist circumference; see Fig. 167-3)
- Class of overweight and obesity determined by BMI, waist circumference, and obesity-related comorbidities (see Table 167-3)
- Readiness to engage in weight loss efforts and potential barriers to success

- Candidacy for treatment with pharmacotherapy, medical devices, or bariatric surgery

Plan*

- Nonpharmacologic lifestyle intervention including low-calorie diet, physical activity, and behavioral modifications
- Determine appropriate weight loss goals based on severity of existing obesity-related complications (see Table 167-4)
- Pharmacotherapy (if appropriate) including specific medication, dose, route, frequency, and duration; specify the continuation and discontinuation of existing therapies (see Table 167-6 and Table 167-8)
- Medical devices (if appropriate) including specific instruction for use, dose, route, duration, and adverse medication reactions (see Table 167-5)
- Monitoring parameters including efficacy (weight loss) and tolerability (medication and/or medical device specific adverse effects) (see Table 167-5 and Table 167-8)
- Bariatric surgery (if appropriate) ensuring specific pre- and post-operative criteria are met.
- Patient education (eg, purpose of dietary and lifestyle modification, medication therapy)
- Self-monitoring of weight—when and how to record results
- Referrals to other providers when appropriate (eg, physician, dietitian, psychologist)

Implement*

- Educate patient regarding health risks associated with overweight and obesity
- Provide patient education regarding all elements of treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence
- Schedule appropriate follow-up (eg, monthly for first 3 months and every 3 months thereafter) based on treatment selected

Follow-Up: Monitor and Evaluate

- Determine weight loss goal attainment
- Presence of adverse medication reactions
- Patient adherence to treatment plan using multiple sources of information

* *Collaborate with patient, caregivers, and other healthcare professionals*

BEYOND THE BOOK

BEYOND THE BOOK

Access the Centers for Disease Control and Prevention (CDC) Overweight & Obesity website found at https://www.cdc.gov/obesity/index.html. Review the latest obesity statistics and recommended strategies to prevent and manage obesity. This website is useful to enhance student awareness of the significant public health impact of overweight and obesity and provides tools to assist in the IMPLEMENT step of the patient care process.

INTRODUCTION

Since 1975, the prevalence of obesity worldwide has nearly tripled.[1] It is now estimated that at seven out of every ten adult women and three of every four adult men have overweight or obesity in the United States, and the number of women with obesity outnumbers those who are overweight.[2] While the rise in obesity among young children ages 2 to 5 years appears to have reached a plateau,[3] the prevalence of obesity persistently increased among 6 to 11 year-olds, 12 to 17 year-olds, and adults over the most recent decade between 1999 and 2000 and 2017 and 2018.[2] The presence of obesity and overweight is associated with a dramatically increased risk for the development of many diseases (Table 167-1), poorer outcomes of comorbid disease states, compromise quality of life, and increased healthcare costs.[4–24] As of 2013, it was estimated that obesity accounted for 28.2% of total health care spending in non-institutionalized adults in the United States), and the total medical costs of obesity were $342.2 billion annually in 2013.[25] National and global initiatives to stem the obesity epidemic have been established through prevention strategies, consensus guidelines, and best practices.[4–6,22,26–34] This chapter reviews the epidemiology, pathophysiology, and therapeutic approaches for the management of obesity. Although nonpharmacologic treatment modalities are discussed, the pharmacotherapy of obesity is highlighted, and the role of pharmacotherapy relative to the other therapeutic options is critically reviewed.

TABLE 167-1

Conditions More Prevalent Among Patients with Obesity

Cancer	**Genitourinary**
Biliary tract system cancer	Chronic kidney disease
Breast cancer (postmenopausal)	End-stage renal disease
Colorectal cancer	Increased serum urate
Cervical cancer	Nephrolithiasis (kidney stones)
Endometrial cancer (premenopausal)	Obesity-related glomerulopathy
Esophageal cancer	Urinary stress incontinence
Gallbladder cancer	**Immune System**
Gastric cardia cancer	Chronic inflammatory reaction
Leukemia	Immune dysfunction
Liver cancer	**Metabolic**
Multiple myeloma	Diabetes mellitus
Meningioma	Gestational diabetes mellitus
Melanoma	Hyperlipidemia
Non-Hodgkin’s lymphoma	Hyperinsulinemia
Ovarian cancer	Hypertriglyceridemia

Pancreatic cancer	Impaired glucose tolerance
Prostate cancer	Low high-density lipoprotein
Rectal cancer	Metabolic syndrome
Renal cell cancer	**Musculoskeletal**
Thyroid cancer	Degenerative joint disease
Cardiovascular	Diffuse idiopathic skeletal hyperostosis
Atrial fibrillation	Disc disease
Cerebral vascular accidents	Fibromyalgia
Chronic heart failure	Flat feet
Coronary artery disease	Gait disturbance
Cor pulmonale	Gout and hyperuricemia
Hypertension	Immobility
Left ventricular hypertrophy	Low back pain/back strain
Myocardial infarction	Osteoarthritis (knee, hips, ankles, feet)
Peripheral vascular disease	Osteoporosis
Peripheral venous insufficiency	Plantar fasciitis
Pulmonary embolism	Sarcopenic obesity
Sudden cardiac death	Total knee arthroplasty (total knee replacement)
Thrombophlebitis	Tendinopathy
Varicose veins	**Neurologic**
Venous thromboembolism	Carpal tunnel syndrome
Ventricular arrhythmias	Idiopathic intracranial hypertension
Dermatologic	Migraines
Acanthosis nigricans	Meralgia paresthetica
Acrochordons (skin tags)	Pseudotumor cerebri
Acne	Stroke
Atopic dermatitis	**Oral Health**

Cellulitis	Dental caries
Hidradenitis suppurativa	Loss of teeth
Intertrigo, carbuncles	Periodontitis
Lymphedema	Xerostomia
Keratosis pilaris	**Psychological**
Panniculitis	Affective disorders
Plantar hyperkeratosis	Anxiety
Psoriasis (women)	Body image disturbance
Status pigmentation of legs	Cognitive dysfunction
Striae distensae (stretch marks)	Depression
Xerosis	Eating disorders
Endocrine and Reproductive	Low self-esteem
Amenorrhea and other menstrual disorders	Social stigmatization
Congenital anomalies	Social isolation
Fetal abnormalities	**Respiratory**
Hirsutism	Asthma
Hyperandrogenism	Chronic obstructive pulmonary disease
Hypogonadism (male)	Dyspnea
Infertility	Hypoventilation syndrome
Precocious thelarche	Obstructive sleep apnea
Polycystic ovary syndrome	Pickwickian syndrome
Pregnancy complications	Pneumonia
Sexual dysfunction	Pulmonary hypertension
Gastrointestinal	Respiratory viral infections (coronavirus, influenza, parainfluenza, metapneumovirus, and rhinovirus)
Altered gut microbiome	

Cholelithiasis	
Gastroesophageal reflux disease	
Hepatic cirrhosis	
Hernias	
Nonalcoholic fatty liver disease	
Pancreatitis	
Nonalcoholic steatohepatitis	
Vitamin deficiencies (fat-soluble and water-soluble vitamins)	

Data from References 4-24.

EPIDEMIOLOGY

One of the global health targets set by the World Health Organization (WHO) is to halt the rise of diabetes mellitus and obesity.[27,35] Obesity in the United States has climbed since the 1960s.[2] The National Health and Nutrition Examination Survey (NHANES) II estimated the prevalence of obesity among adults in the United States was at 15% in 1976 to 1980.[2] By 2017 to 2018, the prevalence of obesity had increased almost threefold and affected 42.4% of the adult population and severe obesity affected 9.2% of the adult population.[2] While the speed with which the prevalence of obesity has increased appears to have somewhat leveled off in recent years, prevention of obesity remains a public health priority due to its high prevalence. If the current trend continues, new projection indicates that by 2030, 78% of the adults in the United States projected will have overweight or obesity and one in every two adults will have obesity.[36] In children, 1 in every 3 children aged 6 to 11 years and 1 in every 2 adolescents aged 12 to 19 years will have overweight or obesity by 2030.[36] Children who are overweight are likely to remain overweight as adults.[37] Furthermore, children and adolescents with overweight or obesity have a higher risk of premature mortality and morbidity as adults.[37] Therefore, childhood and early adulthood are critical intervention periods for prevention of obesity in the next generation and require long-term commitment and investment from all stakeholders.[35] The prevalence of obesity using the 30 kg/m^2 cut point varies by sex and race/ethnicity within the US. Non-Hispanic Asian men (17.5%) and women (17.2%) have the lowest prevalence of obesity compared to other ethnic groups, though they develop obesity-linked complications at lower BMI than other races/ethnicities.[2] The highest prevalence of obesity is observed among non-Hispanic Black women (56.9%) compared with non-Hispanic Black men (41.1%).[2] This disparity is also associated with the level of education. Black women without a college degree are at greater risk of obesity compared with Black men.[38] Educational achievement, which is linked to socioeconomic status, is also correlated with the fraction of people who have obesity. The prevalence of obesity is greatest in those with high school education or less among non-Hispanic White women and men, non-Hispanic Black women, and Hispanic Women.[38]

ETIOLOGY

Obesity occurs when there is increased energy storage resulting from an imbalance between energy intake and energy expenditure over time. The specific etiology for this imbalance in the vast majority of individuals is multifactorial, with genetic and environmental factors contributing to various degrees. In a small minority of individuals, excess weight may be attributed to an underlying medical condition or an unintended effect of a medication.

Genetic Influences

Genetics plays an important role in determining both obesity and distribution of body fat. In some individuals, genetic factors are the primary determinants of obesity, whereas in others, obesity may be caused primarily by environmental factors. The genetic contribution to the actual variance in BMI and body fat distribution is estimated to be up between 40% and 50%.[39] A number of single-gene mutations producing extreme obesity have been identified, but such mutations are rare and account for a relatively small number of the total cases of obesity.[39] The total number and identity of contributing genes are still being determined, as is the means by which the many potential so-called obesity genes interact with each other and with the environment to produce the obese phenotype.

Environmental Factors

Many of the societal changes associated with economic development over the past 50 years have been implicated as potential causes for the increase in the prevalence of obesity.[40] These include an abundant and easily accessible food supply and the material comforts of modern life in Western civilizations, which have contributed to a reduction in physical activity. Advances in technology and automation have resulted in more sedentary lifestyles during both work and leisure time for most individuals. At the same time, there has been a substantial increase in the availability and portion size of high-fat foods, which are aggressively marketed and are often more convenient and less expensive than healthier alternatives. This modern environment has been described by some as "obesogenic" because it is likely to result in a state of positive energy balance in many individuals (Fig. 167-1).[41] Obesity is observed more frequently among individuals within close social networks (eg, siblings, spouses, and friends), with a person's risk of developing obesity increasing dramatically if a friend in their social network has obesity.[42] Cultural factors such as socioeconomic status, and religious beliefs may influence eating habits and body weights. Obesity has also been linked to changes in gut microorganisms and lack of sleep.[40]

FIGURE 167-1

Net energy stores are determined by various inputs and outputs. Simply stated, obesity occurs when there is an imbalance between energy intake and expenditure.

Medical Conditions

Occasionally, patients present with obesity secondary to an identifiable medical condition. Conditions associated with weight gain include iatrogenic and idiopathic Cushing syndrome, growth hormone deficiency, insulinoma, leptin deficiency, and various psychiatric disorders, such as depression, binge-eating disorder, and schizophrenia. Hypothyroidism is often included in this list, but it mostly causes fluid retention (myxedema) and is generally not a cause of obesity. Genetic syndromes that have obesity as a major component are extremely rare and include Prader-Willi, Wilms' tumor, aniridia, genitourinary abnormalities or gonadoblastoma, mental retardation (WAGR), Simpson-Golabi-Behmel, Cohen, Bardet-Biedl, Carpenter, Börjeson, and Wilson-Turner syndromes. The clinician evaluating a patient for obesity needs to be aware of these potential conditions. The physical examination of patients with obesity patients always should include an assessment for secondary causes of obesity, including genetic syndromes.

Medications

An increasing number of medications are associated with unintended weight gain. These include several antiseizure medications (eg, carbamazepine, gabapentin, pregabalin, valproic acid), antidepressants (eg, mirtazapine, tricyclic antidepressants), atypical antipsychotics (eg, clozapine, olanzapine, quetiapine, risperidone), conventional antipsychotics (eg, haloperidol), lithium, hormones (eg, corticosteroids, insulin, medroxyprogesterone), beta adrenergic blockers, sulfonylureas, thiazolidinediones, and antiretrovirals.[43] Although the pharmacologic mechanism responsible for weight gain is usually medication-specific, in most cases the precise mechanism is unknown.

PATHOPHYSIOLOGY

The pathophysiology of obesity involves numerous factors that regulate appetite and energy balance.[29,44,45] Disturbance of these homeostatic functions results in an imbalance between energy intake and energy expenditure.

Appetite

Human appetite is a complex process that is the net result of many inputs within a neural network involving principally the hypothalamus, limbic system, brainstem, hippocampus, and elements of the cortex.[29,44,45] Within this neural network, many neurotransmitters and neuropeptides have been identified that can stimulate or inhibit the brain's appetite network and thereby affect total caloric intake. The first receptor systems found to alter food intake in animals and humans were the biogenic amines. Serotonin, also known as 5-hydroxytryptamine (5-HT), and cells known to respond to 5-HT are found throughout the central nervous system (CNS) and the periphery. Currently, two major noradrenergic receptor subtypes are recognized (α and β), each with multiple subtypes. Histamine and dopamine also demonstrate multiple receptor subtypes, but their role in the regulation of human eating behaviors and food intake is less well documented. Table 167-2 summarizes the major effects of direct receptor stimulation, inhibition, and changes in synaptic cleft amine concentrations on food intake.

TABLE 167-2

Effects of Various Neurotransmitters, Receptors, and Peptides on Food Intake

Anatomic Region	Increased Eating	Decreased Eating
Arcuate nucleus of hypothalamus	• NPY • AgRP	• α-MSH • CART • Leptin • Insulin • GLP-1 • PYY
Paraventricular nucleus of hypothalamus	• NPY • AgRP	• α-MSH, melanocortin • CRH • CCK
Lateral hypothalamus	• Orexin • MCH	
Hypothalamus	• Norepinephrine α_2 • Serotonin 5-HT$_{1A}$	• Norepinephrine α_1 and β_2 • Serotonin 5-HT$_{1B}$ and 5-HT$_{2C}$ • Histamine H$_1$ and H$_3$
Nucleus accumbens	Dopamine	
Brainstem (hindbrain)	• NPY • AgRP • Opioids (especially µ)	• Leptin • α-MSH, melanocortin • CCK
Vagus nerve	Ghrelin	• Leptin • CCK • GLP-1 • PYY

AgRP, agouti-related protein; CART, cocaine-and-amphetamine-regulated transcript; CCK, cholecystokinin; CRH, corticotropin-releasing hormone; GLP-1, glucagon-like peptide-1; MCH, melanocyte concentration hormone; α-MSH, α-melanocyte-stimulating hormone; NPY, neuropeptide Y; PYY, peptide YY.

Data from References 44,45.

Many neuropeptides also influence appetite within the hypothalamus. Most research has focused on the neural projection between parts of the hypothalamus and the arcuate nucleus with signals to the paraventricular nucleus. The key peptides in this projection are thought to include neuropeptide Y and α-melanocyte–stimulating hormone. Neuropeptide Y is the most potent known stimulator of eating, and α-melanocyte–stimulating hormone action at the melanocortin 3 and 4 receptors is one of the crucial inhibitors of eating.[44] The lateral hypothalamus has been referred to as the "hunger" center within the brain. The most prominent of the lateral hypothalamic peptides, orexin, increases food intake stimuli within the lateral hypothalamus.[40] Another important neuropeptide stimulator of eating that principally originates in the lateral hypothalamus is melanocyte-concentrating hormone. Neurons in the lateral hypothalamus use orexin and melanocyte-concentrating hormone to communicate with other neurons throughout the brain and thereby affect a number of functions beyond appetite.[44] Table 167-2 summarizes the major effects of various neuropeptides on food intake.[44,45] Although hunger and satiety functions are thought to be primarily regulated by the hypothalamus, humans eat in response to a broad set of stimuli, including reward, pleasure, learning, and memory.

Peripheral appetite signals also dramatically affect food intake.[45] Leptin, a hormone that is secreted by adipose cells, acts on the arcuate nucleus of the hypothalamus and elsewhere in the brain to decrease appetite and increase energy expenditure.[45] Exogenous leptin administration produces considerable weight loss in leptin-deficient patients; however, recombinant leptin replacement therapy in patients with obesity who are not leptin-deficient has not proved successful because most with obesity appear to be leptin resistant.[44] Figure 167-2 shows the peripheral link that leptin appears to provide in signaling the CNS about the status of fat cell mass.

FIGURE 167-2

Intrinsic hypothalamic hunger and satiety mechanisms are modified by input from fat tissue via leptin, and from the gut via ghrelin, glucagon-like peptide-1 (GLP-1), and other hormones. Additional input is derived by direct sensing of prevailing glucose and other energy signals. The hypothalamus generates signals that are integrated within brain networks, which also receive additional signals. The brain network effects change in energy balance by modifying food intake and energy expenditure.

Other peripheral signals important to the brain's processing of appetite include several gut hormones, notably those released by the intestine in response to passage of digesting food such as glucagon-like peptide-1 (GLP-1), oxyntomodulin, and peptide YY.[45] Each of these hormonal signals suppresses eating. GLP-1 has other effects, most importantly as an incretin, which facilitates release of insulin by pancreatic β cells in response to meal-related glucose. Ghrelin, another important gut hormone that is released from the distal stomach and duodenum, stimulates appetite. An understanding of the relationships among the brain, its many neurotransmitters and neuropeptides, environmental stimulation of brain activities, and other hormones is still evolving.

Energy Balance

The net balance of energy ingested relative to energy expended by an individual over time determines the degree of obesity (Fig. 167-1). An individual's metabolic rate is the single largest determinant of energy expenditure. Resting energy expenditure (REE) is defined as the energy expended by a person at rest under conditions of thermal neutrality. Basal metabolic rate (BMR) is defined as the REE measured soon after awakening in the morning at least 12 hours after the last meal. Metabolic rate increases after eating based on the size and composition of the meal. It reaches a maximum approximately 1 hour after the meal is consumed and returns to basal levels 4 hours after the meal. This increase in metabolic rate is known as the *thermogenic effect of food*. The REE measures the energy costs of the wakeful state and may include the residual thermogenic effect of a previous meal. Physical activity is the other major factor that affects total energy expenditure and is the most variable component. With regard to energy storage, there are two major types of adipose tissue, white adipose tissue (WAT) and brown adipose tissue (BAT). The primary function of WAT is energy storage, whereas BAT is brown because it has much greater mitochondrial density along with high expression of uncoupling proteins that give it the capacity to uncouple oxidative phosphorylation to produce heat and maintain body temperature.[46] BAT is more commonly identified in those who are lean than those with obesity, but its importance for human obesity remains unclear. Both white and brown adipose tissues are highly innervated by the sympathetic nervous system, and adrenergic stimulation via β-adrenergic receptors (β_1, β_2, and β_3) is known to activate lipolysis in fat cells as well as increase energy expenditure in adipose tissue and skeletal muscle.

CLINICAL PRESENTATION

Although obesity is often readily apparent, most patients with obesity seek healthcare only when obesity-associated comorbidities become problematic. The National Institutes of Health (NIH) has established a stratification of weight excess based on associated medical risks.[4,7] These levels of excess weight are defined on the basis of BMI, a measure of total body weight relative to height. Using metric units, BMI (kg/m^2) is defined as weight in kilograms divided by height in meters squared (kg/m^2). Using pounds and inches, BMI (kg/m^2) is estimated as (weight [lb]/height [inches^2]) × 703. Adults with a BMI of 25 to 29.9 kg/m^2 are considered "*overweight*"; the terms *obesity* and *extreme obesity* are reserved for those with a BMI of 30 to 39.9 kg/m^2 and 40 kg/m^2 and over, respectively. The Endocrine Society clinical practice guideline currently classifies children and adolescents older than 2 years of age with a BMI at 120% or above of the 95th percentile or BMI at 35 kg/m^2 or above as having extreme obesity, BMI at the 95th percentile or above as obesity, and those with a BMI between the 85th and 94th percentiles as overweight.[34] Because BMI may overestimate the degree of excess body fat in some clinical situations (eg, edematous states, extreme muscularity, muscle wasting, hydration status, large tumor, short stature), the assessment of body composition in such cases often requires clinical judgment.

① BMI measurement is the practical method of defining obesity in the clinic and in epidemiologic studies; however, it does not always correspond to excess fat. There are well-established differences in the relationship between BMI and obesity-related risks among disparate racial, sex, and ethnic groups. For example, the standard cut points for BMI underestimates risks among Asian patients and utilizing a lower BMI value of 23 kg/m^2 or above to confirm excess body adiposity in this population is recommended.[6,26,47] Across all ethnic groups, men tend to have higher visceral adipose tissues.[48] Central obesity reflects high levels of intra-abdominal or visceral fat, and this pattern of obesity is associated with an increased propensity for the development of hypertension, dyslipidemia, type 2 diabetes mellitus, and cardiovascular disease (sometimes referred to as the "metabolic syndrome") and have an increased cardiometabolic disease risk.[5] Thus, in addition to the absolute excess fat mass, the distribution of this fat regionally in the body has important clinical effects. Intra-abdominal fat is best estimated by imaging techniques such as computed tomography (CT) and magnetic resonance imaging (MRI) but can be approximated through measurement of waist circumference (WC). Clinically, WC is the narrowest circumference measured in the area between the last rib and the top of the iliac crest. Currently in the United States, Canada, and Europe, the definition for high-risk WC is greater than 40 inches (102 cm) in men and greater than 35 inches (89 cm) in women.[7] Specific region- and ethnicity-specific waist circumference thresholds should be used to assess abdominal obesity and disease risks in other populations.[6] Routine determination of WC should be implemented in those with BMIs between 25 and 34.9 kg/m^2 to assess additional metabolic risk.[5,31–33] However, after a patient's BMI reaches 35 kg/m^2, it is not necessary to measure WC because it will likely be elevated and adds little in terms of risk prediction.[32]

② Although BMI and WC are related, each measure independently predicts disease risk. Both measurements should be assessed and monitored during therapy for obesity.[5–7] The risks for development of type 2 diabetes mellitus, hypertension, or cardiovascular disease at various stages of obesity based on BMI or WC are outlined in Table 167-3. Note that increased WC confers increased risk even in normal-weight individuals. A higher prevalence of cardiometabolic abnormalities among normal weight individuals is particularly evident in racial/ethnic minority populations.[49]

TABLE 167-3

Classification of Overweight and Obesity by Body Mass Index, Comorbidity Risk, Waist Circumference, and Associated Disease Risk

				Disease Risk[a] (Relative to Normal Weight and Waist Circumference)	
				Men	
				≤40 in (102 cm)	>40 in (102 cm)
				Women	
	BMI (kg/m^2)	Obesity Class	Comorbidity Risk	≤35 in (89 cm)	>35 in (89 cm)
Underweight	<18.5		Low but other problems	—	—
Normal weight[b]	18.5-24.9		Average	—	High
Overweight	25.0-29.9		Increased	Increased	High
Obesity	30.0-34.9	I	Moderate	High	Very high
	35.0-39.9	II	Severe	Very high	Very high
Extreme obesity	≥40	III	Very severe	Extremely high	Extremely high

BMI, body mass index.

[a] Disease risk for type 2 diabetes mellitus, hypertension, and cardiovascular disease.

[b] Increased waist circumference can also be a marker for increased risk even in persons of normal weight.

Data from WHO Consultation on Obesity (1999: Geneva, Switzerland) & World Health Organization. (2000). Obesity : preventing and managing the global epidemic : report of a WHO consultation. World Health Organization. Available at: https://apps.who.int/iris/handle/10665/42330.

Comorbidities

Obesity and overweight are associated with an increased risk of all-cause mortality and contributed to approximately 7.1% of total death globally.[50] A U-shaped association is noted between BMI and all-cause mortality for patients with diabetes mellitus, hypertension, coronary artery disease, and peripheral artery disease because underweight, obesity, and morbid obesity are all associated with increased risk of cardiovascular diseases (CVD) and mortality.[51] For each standard deviation higher BMI the risk of type 2 diabetes mellitus increases by 67% and coronary artery disease by 20%.[52] While substantial reduction in life expectancy has been predicted in adults with BMIs greater than 35 kg/m^2[53,54] healthy life-years lost due to obesity is estimated to be two to four times greater than total years of life lost.[53] Excessive body fat affects virtually all organ systems. A plethora of evidence continue to link obesity with numerous disease states and health conditions (Table 167-1).[4–24] Therefore, current clinical practice guidelines recommend a “complication-centric approach” for management of obesity.[6,29] It is important for clinicians to assess presence and severity of weight-related complications to determine the appropriate treatment and intensity of weight loss therapy in all individuals with overweight and obesity (Fig. 167-3).[6] Because individuals with obesity are also at risk for developing many malignancies, adherence to routine age- and risk- appropriate cancer screening guidelines is recommended.[29] Furthermore, hypertension, hyperlipidemia, coronary heart disease, cerebrovascular accidents, insulin resistance, glucose intolerance, and diabetes mellitus are all known cardiac risk factors that tend to cluster in individuals with obesity. Aggressive management of these comorbid cardiovascular risk factors and other weight-related complications (eg, sleep apnea, major depression, osteoarthritis, nonalcoholic fatty liver disease) is warranted in an individual with obesity regardless of an individual’s weight loss efforts.[6,7,29]

DIAGNOSIS AND MEDICAL MANAGEMENT OF OBESITY

DIAGNOSIS		COMPLICATION-SPECIFIC STAGING AND TREATMENT		
Anthropometric Component (BMI kg/m²)	Clinical Component	Disease Stage	Chronic Disease Phase of Prevention	Suggested Therapy (based on clinical judgment)
<25 <23 in certain ethnicities waist circumference below regional/ ethnic cutoffs		Normal weight (no obesity)	Primary	• Healthy lifestyle: healthy meal plan/ physical activity
25–29.9 23–24.9 in certain ethnicities	Evaluate for presence or absence of adiposity-related complications and severity of complications • Metabolic syndrome • Prediabetes • Type 2 diabetes • Dyslipidemia • Hypertension • Cardiovascular disease • Nonalcoholic fatty liver disease • Polycystic ovary syndrome • Female infertility • Male hypogonadism • Obstructive sleep apnea • Asthma/reactive airway disease • Osteoarthritis • Urinary stress incontinence • Gastroesophageal reflux disease • Depression	Overweight stage 0 (no complications)	Secondary	• Lifestyle therapy: Reduced-calorie healthy meal plan/physical activity/ behavioral interventions
≥30 ≥25 in certain ethnicities		Obesity stage 0 (no complications)	Secondary	• Lifestyle therapy: Reduced-calorie healthy meal plan/physical activity/ behavioral interventions • Weight-loss medications: Consider if lifestyle therapy fails to prevent progressive weight gain (BMI ≥27)
≥25 ≥23 in certain ethnicities		Obesity stage 1 (1 or more mild-to-moderate complications)	Tertiary	• Lifestyle therapy: Reduced-calorie healthy meal plan/physical activity/ behavioral interventions • Weight-loss medications: Consider if lifestyle therapy fails to achieve therapeutic target or initiate concurrently with lifestyle therapy (BMI ≥27)
≥25 ≥23 in certain ethnicities		Obesity stage 2 (at least 1 severe complication)	Tertiary	• Lifestyle therapy: Reduced-calorie healthy meal plan/physical activity/ behavioral interventions • Add weight-loss medication: Initiate concurrently with lifestyle therapy (BMI ≥27) • Consider bariatric surgery: (BMI ≥35)

a. All patients with BMI ≥25 have either overweight or obesity stage 0 or higher, depending on the initial clinical evaluation for presence and severity of complications. These patients should be followed over time and evaluated for changes in both anthropometric and clinical diagnostic components. The diagnoses of overweight/obesity stage 0, obesity stage 1, and obesity stage 2 are not static, and disease progression may warrant more aggressive weight-loss therapy in the future. BMI values ≥25 have been clinically confirmed to represent excess adiposity after evaluation for muscularity, edema, sarcopenia, etc.

b. Stages are determined using criteria specific to each obesity-related complication; stage 0 = no complication; stage 1 = mild to moderate; stage 2 = severe.

c. Treatment plans should be individualized; suggested interventions are appropriate for obtaining the sufficient degree of weight loss generally required to treat the obesity-related complication(s) at the specified stage of severity.

d. BMI ≥27 is consistent with the recommendations established by the US Food and Drug Administration for weight-loss medications.

TREATMENT

Available treatment options for the chronic management of obesity include reduced caloric intake, comprehensive lifestyle intervention, pharmacotherapy, medical devices, and bariatric surgery.

Desired Outcomes

Weight management is commonly considered successful when a predefined amount of weight has been lost such that a final goal is achieved. However, in the current "complication-centric approach" in obesity management, the primary goal is to ameliorate weight-related complications and ultimately improve patient's health and quality of life rather than a preset decline in body weight.[6] In 2016, comprehensive clinical practice guidelines published by the American Association of Clinical Endocrinologists (AACE) and American College of Endocrinology (ACE), outlined intervention and weight loss goals from at least 5% to 40% based on severity of obesity-related complications (see Table 167-4).[6] The AACE/ACE guideline further outlines the three phase-paradigm of chronic disease prevention and treatment: primary, secondary, and tertiary. The goal of primary phase is to prevent overweight and obesity; the goal of secondary phase is to prevent progressive weight gain or achieve weight loss to prevent complications; the goal of tertiary phase is to achieve sufficient weight loss to improve obesity-related complications and prevent further deterioration. Treatment selection and intensity of obesity intervention varies depending on the phase of prevention and treatment in which the patient resides. If improvement in type 2 diabetes mellitus, dyslipidemia, hypertension, and polycystic ovary syndrome are primary goals, then the recommended weight loss goals is at least 5% to 15% or more.[6] For patient with steatohepatitis, the recommended weight loss goal is 10% to 40% in order to reduce inflammation and fibrosis of the liver.[6] Success may also include end points of decreasing the rate of weight gain or maintaining a weight-neutral status. All too often patients expect to lose weight overnight, only to be disappointed. Thus, it is important to set a time course for the plan. Numerous web-based resources for supporting both patient and practitioner weight-management activities are available.[7,55–58]

TABLE 167-4

Tertiary Prevention Treatment Goals Based on Diagnosis in the Medical Management of Patients with Overweight or Obesity[a]

Diagnosis	Weight Loss Goals	Clinical Goals
Urinary stress incontinence	5% to 10% or more	Reduced frequency of incontinence episodes
Metabolic syndrome	10%	Prevention of type 2 diabetes mellitus
Prediabetes	10%	Prevention of type 2 diabetes mellitus
Gastroesophageal reflux disease	10% or more	Reduced symptoms frequency and severity
Female infertility	10% or more	Ovulation, pregnancy, and live birth
Asthma/reactive air way disease	7% to 8% or more	Improved in forced expiratory volume at 1 second (FEV1), improved symptoms
Obstructive sleep apnea	7% to 11% or more	Improved symptoms, decreased apnea-hyponea index
Osteoarthritis	≥10% (5%-10% or more when coupled with exercise)	Improved symptoms, increased function
Type 2 diabetes mellitus	5% to ≥15%	Reduced A1c, reduced number and/or doses of diabetes medications, diabetes remission (if diabetes duration is short)
Dyslipidemia	5% to ≥15%	Lowered triglycerides, raised HDL-C, lowered non-HDL-C
Hypertension	5% to ≥15%	Lowered blood pressure, reduced number and/or doses of antihypertensive medications
Polycystic ovary syndrome	5% to ≥15%	Ovulation, regularization of menses, reduced hirsuitism, enhanced insulin sensitivity, reduced serum androgen levels
Nonalcoholic fatty liver disease		
• Steatosis • Steatohepatitis	• 5% or more • 10% to 40%	• Reduced intrahepatocellular lipid • Reduced inflammation and fibrosis
Depression	Uncertain	Improved depressive symptoms and depression scores

A1c, glycated hemoglobin A1c; HDL-C, high density lipoprotein cholesterol

[a]Patients with BMI ≥ 25 kg/m^2 (≥ 23 kg/m^2 in certain ethnicities)

Adapted from Garvey WT, Mechanick JI, Brett EM, et al. American Association of Clinical Endocrinologist and American College of Endocrinology Comprehensive Clinical Practice Guidelines for medical care of patients with obesity. Endocr Pract. 2016;3:1–203.

General Approach to Treatment

To achieve meaningful weight loss goals, successful obesity treatment plans require incorporation of comprehensive lifestyle interventions such as healthy diet, adequate physical activity, and behavioral modifications as the cornerstone of weight management.[5,6,26,28,29,31–33] Psychological interventions such as cognitive therapy or stress management to address the emotional relationship with food may help further promote adherence, intrinsic motivation and treatment success.[32,33] Once the need for weight loss has been determined, the clinician needs to assess a patient's readiness to engage in weight loss efforts and identify any potential barriers to success. They need to initiate a dialogue with each patient who has overweight or obesity to ensure they understand the potential health consequences of excess body weight and benefits of appropriate weight management. Specific weight goals should be established that are consistent with medical needs, weight-related complications, and the patient's personal desire.[6] Patients should not be allowed to attain an abnormally low body weight (ie, less than their estimated ideal body weight).

③ Patients seeking help for obesity do so for many reasons, including improvement in their quality of life, a reduction in associated morbidity, and increased life expectancy. Because weight stigma is prevalent in the western culture, numerous individuals seek therapy for obesity primarily for cosmetic purposes and often have unrealistic goals and expectations. Aggressive marketing of weight loss programs, therapies, and diets—parallel to the fashion industry's standards of desirable body profiles—has led many individuals to set impossible goals and expectations. Often, these individuals will go to extreme measures to achieve weight loss. Consequently, clinicians must be careful to fully discuss the risks of therapies and to clearly define the achievable benefits and magnitude of weight loss. Patients with obesity should be redirected away from trying to achieve an "ideal weight" to the more realistic goal of modest (eg, loss of 5-10% of body weight) but sustained, medically relevant weight loss. In practice, goals should be set based on many factors, including initial body weight, patient motivation and desire, presence of obesity-related comorbid conditions, and age. The Look Action for Health in Diabetes (AHEAD) study found that patients with diabetes mellitus who maintained weight loss of at least 7% with intensive lifestyle modifications for a period of almost 10 years did not experience a reduced incidence of cardiovascular events, but they did have a reduced need for diabetes mellitus medications and improvement in physical function, lipids, blood pressure, kidney disease, sleep apnea, fitness, and depression.[59] When behavioral-based weight loss intervention is incorporated, with or without medication therapy, patients are able to achieve more weight loss and have a lower risk of developing diabetes mellitus.[60] In patients with overweight and obesity with diabetes mellitus, lifestyle modification with sustained weight loss of greater than 5% improves HbA1c level and ameliorates hyperglycemia, hyperlipidemia, and hypertension within a year.[61] For individuals with obesity who have gastroesophageal reflux disease, a 10% or more weight reduction may be required to improve symptoms.[6] This highlights the importance of defining end points and measures of success in any weight-loss plan.

④ Weight-loss interventions must be founded on lifestyle changes, such as a modification in eating practices; complemented by medication therapy, if indicated; and in some cases, surgery. Before recommending any therapy, the clinician must evaluate the patient for the presence of secondary causes of obesity.[62] If a secondary cause is suspected, then a more complete diagnostic workup and the initiation of appropriate therapy may be warranted. The next step in patient evaluation is to determine the presence and severity of other medical conditions that are either directly associated with obesity (eg, diabetes mellitus, cardiovascular diseases, uncontrolled hypertension) or that have an impact on therapeutic decision making (eg, history of pancreatitis, cardiac arrhythmia, seizure disorders, concurrent medications).[6,29] The Endocrine Society Clinical Practice Guideline for the Pharmacological Management of Obesity emphasizes that clinicians should always consider the potential weight-altering effects of all medications a patient is receiving for the management of comorbid conditions and select medications that are weight-neutral or promote weight loss (strong recommendation with moderate quality evidence).[29] For example, in patients with type 2 diabetes mellitus, antidiabetic agents that promote weight loss (eg, metformin, glucagon-like peptide-1 analogs, sodium-glucose-linked transporter-2 inhibitors) are preferred. Appropriate laboratory tests to exclude or quantify the degree of specific conditions such as diabetes mellitus, liver dysfunction, and nephropathy should be performed as indicated by the history and physical examination. Based on the outcome of this medical evaluation, the patient should be counseled on treatment options, benefits, and risks. Ultimately, lifelong therapeutic goals should consist of maintenance of reduced body weight and prevention of weight gain.

Nonpharmacologic Therapy

Nonpharmacologic therapy, including reduced caloric intake, increased physical activity, and behavioral modification is the mainstay of obesity management. This combination, also known as lifestyle therapy, is recommended for all patients with overweight and obesity by the ACC/AHA Guideline on the Primary Prevention of Cardiovascular Disease,[5] The Endocrine Society Clinical Practice Guidelines for the Pharmacological Management of Obesity (graded as strong recommendation with high quality evidence)[29] and the AACE/ACE Guidelines for the Medical Care of Patients with Obesity (grade A recommendation with the best level of evidence).[6] Weight loss will require major effort on the part of the patient to change their lifestyle and comply with the management plan. If the patient is not ready to meet these expectations, then early counseling will reduce the chance of frustration for the patient, clinician, and possibly other family members. Providing basic education can lead to a substantial change in motivation and desire to lose weight and improved compliance.

Reduced Caloric Intake

Current adult guidelines recommend reduced energy intake through adherence to a low-calorie diet (LCD).[5,6] The LCD should provide a daily energy deficit of 500 to 750 kcal (2,100-3,150 kJ), which generally correlates to a total intake of 1,200 to 1,500 kcal/day (5,000-6,300 kJ/day) for women and 1,500 to 1,800 kcal/day (6,300-7,550 kJ/day) for men. Individuals with severe obesity will require more energy, at least at the start of dietary restriction. Adherence to the LCD results in an average weight loss of 8% after 6 months.[7]

Numerous diet and nutrition plans are available to aid patients in their pursuit of weight loss, and current guidelines allow for choice among many potential evidence-based diet plans.[6,7,63] Popular diets include moderate energy-deficient plans (eg, DASH [Dietary approaches to Stop Hypertension], Mediterranean, Weight Watchers, LEARN [Lifestyle, Exercise, Attitude, Relationships, Nutrition], Jenny Craig), vegetarian-based plans (eg, Ornish), and low carbohydrate plans (eg, Zone, Atkins). Short-term weight loss is considerable for almost all diet plans. However, long-term weight loss and maintenance of weight loss are less promising, primarily because of difficulty with adherence. Therefore, the choice of diet plan should be determined based on patient-specific preferences, health status, and ability to consistently adhere to the specific recommendations of the diet.[6] A meta-analysis of 121 clinical trials assessing the efficacy of various diets concluded that differences in weight loss among popular named diets are not clinically significant,[64] highlighting the general consensus that macronutrient composition of the diet may not be as important as consistent adherence to reduced energy consumption. Time restricted eating (TRE), defined as consuming all calories within a restricted time window (eg, 6-8 hours) and fasting during the rest of the day, has recently become a popular diet intervention for weight loss and other health benefits. Although short-term weight loss data are promising, long-term data on the sustained efficacy, ability for patients to adhere to the required lifestyle changes, and safety in patients with obesity-related comorbidities are limited.[65]

Very-low-calorie diets, providing less than 800 kcal/day (3,350 kJ/day), are generally not recommended.[7] Although very-low-calorie diets can often result in substantial early weight loss, long-term results have been disappointing because it is difficult for individuals to maintain compliance. Additionally, very-low-calorie diets require intensive medical monitoring and should only be used in certain situations under the supervision of an experienced clinician. Regardless of the diet program, it is clear that energy consumption must be less than energy expenditure to achieve weight loss (see Fig. 167-1). The challenge is to develop a diet plan that leads to consistent adherence by the patient and sustained weight loss and maintenance.

Comprehensive Lifestyle Intervention

Comprehensive lifestyle intervention encompasses the combination of reduced energy intake, increased physical activity, and behavioral modification. Increased physical activity is an important component in achieving the state of greater energy expenditure than energy intake that is necessary to lose weight and maintain weight loss. Weight loss is modest when increased physical activity is attempted as monotherapy. However, when it is combined with reduced energy intake and behavior modification, it can augment weight loss and improve obesity-related comorbidities and cardiovascular risk factors.[5,7] Aerobic physical activity for at least 150 minutes per week, completed over three to five days is recommended for adults.[6,66] Greater levels (ie, 200-300 min/wk) may be required to augment weight loss and maintain lost weight. Patients should be advised to start slowly and gradually increase intensity. All patients with obesity should receive a medical examination before embarking on a physical activity program.

Current adult guidelines recommend initiation of a comprehensive lifestyle program to help patients with overweight and obesity adhere to the prescribed LDC and increased physical activity per week (NHLBI Grade A; strong recommendation).[5,6] For patients who have successfully lost weight during the first 6 months, long-term participation in a comprehensive lifestyle program is recommended. The primary aim is to help patients choose lifestyles that are conducive to safe and sustained weight loss. Most such programs use self-monitoring of diet and exercise to increase patient awareness of behavior and as a tool for the clinician to determine patient compliance as well as patient motivation. High-intensity comprehensive lifestyle interventions that include a reduced-calorie diet, increased exercise, and in-person behavioral counseling sessions result in an average weight loss of 8 kg (17.6 lb) after 6 months.[7]

Bariatric Surgery

⑤ Consistent with the growing obesity epidemic, the demand for bariatric surgery has increased drastically over the past two decades. Surgery currently remains the most powerful and effective intervention for the treatment of obesity.[67,68] Current clinical practice guidelines recommend that surgical intervention be reserved for adults with extreme obesity (BMI ≥ 40 kg/m^2 or BMI > 37.5 kg/m^2 in Asian Americans) without other comorbidity, or BMI at 35 kg/m^2 or above (BMI 32.5 – 37.4 kg/m^2 in Asian Americans) with at least one or more major comorbidity such as hypertension, type 2 diabetes mellitus, or obstructive sleep apnea (NHLBI Grade A; strong recommendation).[6,26,29,68] Surgery may also be advocated to adults with BMI between 30 kg/m^2 and 34.9 kg/m^2 (27.5-32.4 kg/m^2 in Asian Americans) with diabetes mellitus or metabolic syndrome, as a similar efficacy and safety profile for improving type 2 diabetes mellitus and metabolic disorders is observed among bariatric patients with a BMI below or above 35 kg/m^2.[26,69] This has led to use of the term "metabolic surgery" with focus on treating metabolic diseases independent of body weight.[68] Bariatric surgery is also endorsed by the American Academy of Pediatrics for severe obesity. For adolescents, the American Society for Metabolic and Bariatric Surgery recommends bariatric surgery can be considered in youth (ages 13 to 18) with BMI ≥ 35 kg/m^2 or ≥ 120% of the 95th percentile for age, whichever is lower, with a severe comorbidity, or in youth with BMI ≥ 40 kg/m^2 or ≥ 140% of the 95th percentile for BMI, whichever is lower, with any obesity-related comorbidity.[69]

Surgical weight loss options should only be considered in patients who have met the eligibility criteria and have failed other recommended methods for weight loss. It is critical for bariatric surgical candidates to fully understand the surgical risks and be able to commit fully to the extensive postoperative care plan, follow-ups, and necessary lifelong vitamin supplementation, medical monitoring (including costs required), dietary, lifestyle and behavioral adjustments to ensure the long-term success of the procedure.[68]

Appropriate selection of a bariatric procedure should be individualized based on goals of therapies, available expertise, patient preferences and inherent risks. The four available surgical procedures currently endorsed by the American Society of Metabolic and Bariatric Surgery are (1) adjustable gastric banding, (2) sleeve gastrectomy, (3) biliopancreatic diversion with duodenal switch, and (4) conventional Roux-en-Y gastric bypass. The adjustable gastric banding and sleeve gastrectomy are designed to reduce the volume of the stomach and thus restrict the rate of nutrient intake. The biliopancreatic diversion with duodenal switch is primarily malabsorptive in nature, and the length of the diversion determines the extent of nutrient malabsorption. This hybrid procedure combines a restrictive approach with a degree of malabsorption induced by reducing the size of the stomach pouch and causing food to bypass parts of the small intestine. Techniques that involve redirection of the flow of nutrients so as to have humoral and malabsorptive effects, generally yield greater and longer lasting weight loss than the purely restrictive methods.[67] The sleeve gastrectomy has increased in its popularity worldwide and is currently the most common procedure performed in the United States.[68] Resection of the gastric segment from sleeve gastrectomy also removes the endocrine cells, which alters neuro-humoral activity and results in earlier satiety and improvements in glucose metabolism. The amount of total body weight loss and remission of comorbidities is proportional to intestinal bypass, which is expected from the metabolic effect of the surgery [eg, adjustable gastric banding (20-25%) < sleeve gastrectomy (25-30%) < Roux-en-Y gastric bypass (30-35%) < duodenal switch (35-45%)].[68] Patients usually achieve the lowest post-bariatric weight from 1 to 2 years after bariatric surgery.

After 5 years, patients with type 2 diabetes mellitus with BMI of 27 to 43 kg/m^2 who undergo gastric bypass surgery lose more (23%) of their initial body weight compared to patients who receive sleeve gastrectomy (19%) and patients who receive intensive medical therapy (5%).[70] Results from gastric bypass appear at least as promising among adolescents, for whom the likelihood for, and durability of remission from comorbid conditions is often greater than observed in adults.[71,72] The extent of weight loss and the potential for weight regain after bariatric surgery is multifactorial as metabolic, anatomic, and lifestyle changes can all impact the outcome of the procedure. Bariatric surgeries are now considered among the safest abdominal surgical procedures performed in the United States today; the operative 30-day mortality rates for gastric bypass and sleeve gastrectomy are 0.2% and 0.1%, respectively.[67] Some of the most common early surgical complications are gastric and anastomotic leaks, bleeding, wound infections, and pulmonary emboli. Due to the disruption of the normal gastric anatomy and physiology, postsurgical patients are often at risk for severe micronutrient deficiencies (eg, vitamin B$_{12}$, vitamin B$_1$, vitamin K, zinc, copper, folate, iron, calcium) as well as deficiencies in fat soluble vitamins such as vitamins A, D, E and K due to fat malabsorption.[68] Therefore, empiric supplementation with daily adult multivitamin plus minerals, elemental calcium, vitamin D, folic acid, thiamine, elemental iron, and vitamin B$_{12}$ is essential to prevent nutritional deficiencies in bariatric patients.[68] Because many commercial dietary supplements products are adulterated with compounds that are not included in the original manufacturer's label, use of supplements verified by the

US Pharmacopeia (https://www.quality-supplements.org/verified-products), or other brands that have been safely and effectively tested in clinical trials are recommended.[68] All bariatric surgical patients should undergo life-long monitoring of nutritional deficiencies after the procedure. Profound weight loss resulting from bariatric surgery provide multitude of health benefits, which are often accompanied by dramatic improvements, and sometimes complete resolution, of many obesity-related complications.[67,68]

Significant reduction in risks of myocardial infarction, cardiovascular deaths, as well as the incidence of type 2 diabetes mellitus, hypertension, dyslipidemia, and cancer occur after adult's bariatric surgery.[14,67,70,73,74] It has long been known that bariatric surgery improves microvascular diseases,[75] and substantially reduces macrovascular disease and mortality in patients with type 2 diabetes mellitus and severe obesity.[73] Patients who undergo Roux-en-Y gastric bypass surgery are expected to have a 40% decrease in all-cause mortality, 60% decrease in mortality due to cancer, 92% decrease in mortality due to diabetes mellitus, and 56% decrease in mortality due to coronary artery disease at 12 years.[74] An increase in life expectancy is also expected after bariatric surgery, regardless of the type of bariatric procedure.[76] Metabolic surgery can prolong median life expectancy by 6.1 years and substantial survival benefit is seen in patients with pre-existing diabetes mellitus than those without after surgery (9.3 years vs 5.1 years gain in median life expectancy).[76] Every 1% increase in metabolic surgery utilization rate is estimated to yield 5.1 million to 6.6 million potential life-years saved.[76] Despite the expenses of the bariatric procedure, bariatric surgery is a cost-saving alternative to conventional management over the lifetime for patients who suffer from severe obesity.[77]

After experiencing weight loss, many gastric surgery patients are able to discontinue pharmacotherapy for glucose lowering, dyslipidemia, hypertension, and reduce medication costs.[67,68,70] However, the need for use of proton-pump inhibitors are often increased as a prophylactic therapy for anastomotic ulcers.[68,78] It is imperative for clinicians to recognize that bariatric interventions not only alter nutrient absorption but also may impede medication absorption and can cause potential serious consequences.[78] Achlorhydria, reduced contact time with digestive enzymes, reduced surface area for intestinal and gastric absorption, reduced bile acid exposure after bariatric surgery can lead to altered absorption, distribution, metabolism, and/or elimination of many medications.[78] Use of direct oral anticoagulant (eg, apixaban, rivaroxaban) and non-steroidal anti-inflammatory drugs (eg, ibuprofen) should be avoided after surgery.[78] Reduced serum concentrations may be observed for some antimicrobials, antidepressants, selective serotonin reuptake inhibitors (SSRIs), antipsychotics and tamoxifene.[78] Furthermore, concurrent administration of proton-pump inhibitors may also alter bioavailability of weak basic medications such as antifungals (eg, posaconzale),[78] certain antibiotics and some cardiovascular medications (eg, digoxin) as well as hinder the absorption of micronutrients.[78] Therefore, clinicians need to recognize that the standard dosage regimens recommended for presurgical patients may need to be adjusted. Switching from solid medications to opened capsules or liquid formulations (without high sugar loads) for post-surgical patients may be beneficial when inadequate clinical response is observed.[78] Long-term close therapeutic monitoring of all orally administered medications after surgery, particularly those with narrow therapeutic ranges (eg, warfarin, levothyroxine, lithium) is highly recommended because dosage form selection, dose conversion, or therapeutic interchange may be necessary to avoid or minimize absorption problems and ensure optimal patient outcomes.[68,78] Controlled-release formulations may be used after surgery but close monitoring is needed.[78] With increased fertility rate and decreased absorption of oral contraceptives after bariatric surgery, alternative non-oral contraceptive is recommended for all reproductive-aged women who have undergone surgery.[68,78] Women who desire to conceive should wait at least 12 to 18 months after bariatric surgery to ensure stable weight and balance nutrition is achieved.[68]

Implantable Medical Devices

Despite meeting the medical necessity for bariatric surgery, some individuals may not qualify as surgical candidates or may choose to not undergo the procedure. Medical devices may fill the existing treatment gap in obesity management and may address the unmet needs in these individuals. Currently, there are six FDA-approved medical devices for weight reduction involving electrical stimulation, gastric emptying, gastric balloon systems, or superabsorbent hydrogel (Table 167-5).[79–84] Each of these devices are fully reversible and are designed to work in conjunction with prescribed diet and exercises programs. A patient's ability to provide appropriate follow-up is essential to enhance the safety and to avoid complications related the devices. Unfortunately, once the device is removed, patients will often regain the lost weight.

TABLE 167-5

FDA-Approved Medical Devices for Weight Loss

Device	Mechanism of Action	BMI Indication	Contraindications	Weight Loss Outcomes	Adverse Medication Reactions	Comments
Gastric Emptying System						
AspireAssist®[79,80]	An implanted percutaneous gastrostomy aspiration tube removes approximately 25-30% of the meal from stomach 20-30 minutes after ingestion	Adult age ≥ 22 with BMI 35-55 kg/m^2	- Uncontrolled hypertension - Bulimia - Binge eating disorder - Night-eating syndrome - Previous abdominal surgery - Esophageal stricture, gastric obstruction, gastroparesis - Inflammatory bowel disease - Stomach ulcer - History of serious pulmonary or cardiovascular disease - Coagulation disorders - Anemia - Chronic abdominal pain - Pregnancy or lactation, or desire to become pregnant	%TBWL across trials demonstrated 17.8%, 18.3%, 19.1% and 18.6% after 1 year, 2 years, 3 years, and 4 years, respectively[80]	- Abdominal pain - Indigestion - Nausea - Vomiting - Constipation - Diarrhea - Peristomal granulation tissue - Peristomal irritation and inflammation	• Patient must take extra time to chew thoroughly and drink sufficient liquid with each meal to ensure proper aspiration • Frequent medical visits are also necessary to monitor device use and weight loss and to provide counseling on lifestyle therapies • The device contains a safety feature to keep track the number of times the drain tube is connected to the port and automatically stops working after 115 cycles (approximately 5-6 weeks of therapy) to ensure proper use
Electrical Stimulation System						
Maestro® Rechargeable System[79]	A neurometabolic therapy, deliver via a place-maker like device	• Age ≥ 18 with BMI 40-45 kg/m^2	- Liver cirrhosis - Portal hypertension	%TBWL after 1 year of therapy is	- Neuroregulator site pain	• The implanted neuroregulatory is controlled by

	that is implanted on the vagal trunk. The device is designed to intermittently block the communication with the vagus nerve (vBloc) through the delivery of electrical impulse to increase satiety and improve food related cognitive restraints.	- OR - Age ≥ 18 with BMI 35-39.9 kg/m^2 with at least 1 comorbidity	- Esophageal varices - Hiatal hernia - Planned MRI or diathermy - Permanently implanted, electrical-powered medical device (ie, pacemaker, defibrillator, neurostimulator)	9.2% and excess body weight is 24.4%.	- Nausea - Abdominal pain - Heartburn - Dyspepsia	the clinician with an external programming device to deliver 12 to 15 hours of intermittent nerve block. Battery is recharged daily for 30 minutes. - Once the device is turn-off, patient often will regain the weight lost
Gastric Balloon System						
Orbera Intragastric Balloon[79,81–83]	Endoscopically placed intragastric balloon device designed to occupy space in the stomach to reduce hunger and improve appetite control.	- Orbera® - Adult age ≥ 22 with BMI 30-40 kg/m^2 - Orbera365™ - Adults with BMI > 40 kg/m^2 - OR - Adult with BMI ≥ 35 kg/m^2 with comorbidities - OR - Adults with BMI between 27 and 50 kg/m^2 who failed to achieve and maintain weight loss with a supervised weight-controlled program	- Previous gastric surgery - Hiatal hernia - Coagulation disorder - A potential bleeding lesion of the upper gastrointestinal tract - Alcohol or drug misuse - Severe liver disease - Pregnancy or lactation, or desire to become pregnant - Any contraindication to endoscopy	%TBWL after 1 year of therapy is 11.3%.[81]	- Abdominal pain - Nausea - Vomiting - Dysphagia - Heartburn - Early explantation - Gastric ulcer - Deflation - Migration - Perforation - Hyperinflation of balloon - Acute pancreatitis	- The device placement is intended to be temporarily. After 6 months (Orbera®) or 12 months (Orbera365™), the balloon is punctured and removed through the mouth via a grasping device - Patients who fail to remove the device after 6 months (Orbera®) or 12 months (Orbera365™), will be at increased risk of intestinal obstruction due to migration of the deflated balloon - Aggressive symptoms control with

						triple antiemetic medications in the early period after insertion ● Use of proton pump inhibitor and avoidance of non-steroidal anti-inflammatory agents during treatment ● Weight regain occurs after device removal
[a]The ReShape Integrated Dual Balloon System[79,82,83]	Endoscopically placed intragastric balloon device designed to occupy space in the stomach to reduce hunger and improve appetite control	Adult age 22 -60 with BMI 30- 40 kg/m^2 with at least 1 comorbidity	- Prior gastrointestinal or bariatric surgery - Inflammatory intestinal or bowel disease - Large hiatal hernia - Delayed gastric emptying - Upper gastrointestinal bleed - Coagulation disorder - Severe liver disease - Active *Helicobacter pylori* infection - A structural abnormality in the esophagus or pharynx - Use of anticoagulants or anti-inflammatory agents - Pregnancy or lactation, or desire to become	%TBWL after 6 months of therapy is 15.4%	- Abdominal pain - Nausea - Vomiting - Heartburn - Gastric ulcer - Deflation - Perforation - Dysphagia - Gastric bleeding - Hyperinflation of balloon - Acute pancreatitis	● The device placement is intended to be temporarily and should be removed 6 months after insertion as the device will deflate over time ● Patients who fail to remove the device after 6 months will be at increased risk of intestinal obstruction due to migration of the deflated balloon ● Aggressive symptoms control with triple antiemetic medications in the early period after insertion ● Use of proton pump inhibitor and avoidance of non-steroidal anti-

			pregnant - Any contraindication to endoscopy				inflammatory agents during treatment ● Patients currently taking selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs), and monoamine oxidase inhibitors (MAOIs) should use this device with caution due to the potential for balloon rupture and release of methylene blue which with these concurrent therapies can increase risk of developing serotonin syndrome ● Weight regain occurs after device removal
Obalon Balloon System™[79,83]	Sequentially swallowed balloon device designed to occupy space in the stomach to reduce hunger and improve appetite control. A total of 3 balloons are placed over 3 months.	Adult age ≥ 22 with BMI 30-40 kg/m^2	- Any structural or functional abnormality in the esophagus, pharynx, stomach, intestines, or any portion of the gastrointestinal tract - Prior bariatric	%TBWL after 6 months of therapy is 6.8%	- Abdominal pain - Nausea - Vomiting - Heartburn - Bloating - Deflation - Gastric ulcer - Hyperinflation of balloon		● The only intragastric balloon that does not require endoscopic placement. The balloon is encapsulated, attached to a tube, and swallowed

			surgery - Inflammatory and other conditions of the gastrointestinal tract - Active *Heliocobacter pylori* infection - Bulimia, binge eating or other eating disorders - Use of gastric irritants such as NSAIDs and aspirin - Use of anti-platelets or anticoagulants - Irritable bowel syndrome or other inflammatory bowel disease - Taking medications on specified hourly intervals that may be affected by changes in gastric emptying (eg, anti-seizure or anti-arrhythmic medications) - Alcohol or drug misuse - Pregnancy or lactation, or desire to become pregnant			under provider supervision • The device placement is intended to be temporarily and should be endoscopically removed after 3 to 6 months • Aggressive symptoms control with triple antiemetic medications in the early period after insertion • Use of proton pump inhibitor and avoidance of non-steroidal anti-inflammatory agents during treatment • Weight regain occurs after device removal
Nonsystemic Oral Superabsorbent Hydrogel						
Plenity®[84]	Oral capsule releases carboxymethylcellulose and citric acid hydrogel when taken with water. The particles rapidly	Adult with BMI 25-40 kg/m^2	- Allergic reaction to cellulose, citric acid, sodium stearyl fumarate,	%TBWL demonstrated 6.4% and 9.5% after 6 months and	- Abdominal pain - Diarrhea - Abdominal distension	Take three capsules (2.25 g total) orally twice daily, administer 20 to 30 minutes before lunch

	absorb water and mix with ingested food, which expands to ¼ of the stomach volume, to create a sensation of satiety to reduce hunger and improve appetite control.		gelatin, or titanium dioxide - Pregnancy	48 weeks, respectively	- Infrequent bowel movements - Flatulence - Constipation	and dinner

BMI: Body Mass Index; TBWL: Total Body Weight Loss

[a] As of January 2019, ReShape has been voluntary withdrawn from the market due to marketing reasons.

Pharmacologic Therapy

⑥⑦ According to current guidelines, pharmacotherapy is an adjunct to comprehensive lifestyle intervention in adults who are motivated to lose weight, have failed to achieve or sustain weight loss with lifestyle changes alone, and have a BMI more than or equal to 30 kg/m^2 or a BMI more than or equal to 27 kg/m^2 with at least one weight-related comorbidity (Graded as a strong recommendation with high quality evidence).[6,29] Furthermore, patients who meet the BMI requirements and have a history of failed attempts to lose weight or maintain weight loss with comprehensive lifestyle intervention alone may also be candidates for pharmacotherapy.[29] Long-term pharmacotherapy may have a place in the treatment of obesity for patients who have no obvious contraindications to approved medication therapy, as the likelihood of weight regain after treatment discontinuation is quite high. Table 167-6 lists FDA-approved pharmacotherapeutic agents currently available for management of overweight and obesity.

TABLE 167-6

FDA-Approved Pharmacotherapeutic Agents for Weight Loss

Medication	Brand Name	Initial Dose	Usual Range	Special Population Dose	Comments
Gastrointestinal Lipase Inhibitor					
Orlistat	Xenical®	120 mg three times daily with each main meal containing fat	120 mg three times daily with each main meal containing fat	120 mg three times daily is approved for adolescents ages 12 or greater with BMI for age equivalent to 30 kg/m^2 in adults	- Approved for long-term use - Take during or up to 1 hour after the meal - Omit dose if meal is occasionally missed or contains no fat
Orlistat	Alli® [a]	60 mg three times daily with each main meal containing fat	60 mg three times daily with each main meal containing fat		Same as Xenical®

Phentermine–Topiramate Combination					
Phentermine and topiramate extended release	Qsymia®	3.75 mg of phentermine and 23 mg of topiramate once daily for 14 days; then increase to 7.5 mg of phentermine and 46 mg of topiramate once daily	7.5 mg of phentermine and 46 mg of topiramate once daily to a maximum dose of phentermine 15 mg and topiramate 92 mg once daily	Maximum dose for patients with moderate or severe kidney impairment or patients with moderate hepatic impairment is 7.5 mg of phentermine and 46 mg of topiramate	• Approved for long-term use • Take dose in the morning to avoid insomnia • Controlled substance: C–IV
Naltrexone-Bupropion Combination					
Bupropion and naltrexone extended release	Contrave®	8 mg naltrexone/90 mg bupropion (1 tablet) once daily in the morning for 1 week; then 8 mg naltrexone/90 mg bupropion twice daily (morning and evening) for 1 week; then 16 mg naltrexone/180 mg bupropion in the morning and 8 mg naltrexone/90 mg bupropion in the evening for 1 week; then 16 mg naltrexone/180 mg bupropion twice daily (morning and evening)	16 mg naltrexone and 180 mg bupropion (2 tablets) twice daily	• Maximum dose for patients with moderate or severe kidney impairment is 8 mg naltrexone/90 mg bupropion (1 tablet) twice daily • Maximum dose for patients with hepatic impairment is 8 mg naltrexone/90 mg bupropion (1 tablet) once daily in the morning	• Approved for long-term use • Do not take dose with high-fat meal
Glucagon-Like Peptide-1 Antagonists					
Liraglutide	Saxenda®	• 0.6 mg once daily for 1 week • 1.2 mg once daily for 1 week • 1.8 mg once daily for 1 week • 2.4 mg once daily for 1 week • 3.0 mg once daily for 1 week	3 mg once daily	Use with caution in mild, moderate, and severe kidney and hepatic impairment. Dose escalation to 3.0 mg once daily is approved for adolescents ages 12 or greater with weight 60 kg (132 lb) or greater and BMI for age equivalent to 30 kg/m^2 in adults	• Approved for long-term use • Inject subcutaneously in the abdomen, thigh, or upper arm
		Administered by subcutaneous injection			Administer at any time of day without regard to the timing

					of meals
Semaglutide	Wegovy™	- 0.25 mg once weekly for 4 weeks - 0.5 mg once weekly for 4 weeks - 1 mg once weekly for 4 weeks - 1.7 mg once weekly for 4 weeks - 2.4 mg once weekly - Administered by subcutaneous injection	2.4 mg once weekly		- Approved for long-term use - Inject subcutaneously in the abdomen, thigh, or upper arm - Administer at any time of day without regard to the timing of meals
Melanocortin 4 (MC4) Receptor Agonist					
Setmelanotide	**Imcivree™**	- Adults and adolescents > 12 years: - 2 mg once daily for 2 weeks, then increase to 3 mg once daily if tolerated and additional weight loss is desired (or decrease to 1 mg once daily based on tolerability) - Children aged 6 to < 12 years: - 1 mg once daily for 2 weeks, then increase to 2 mg once daily if tolerated (or decrease to 0.5 mg once daily based on tolerability), then increase to 3 mg once daily if tolerated and additional weight loss is desired - Administered by subcutaneous injection	2-3 mg once daily	Not recommended for patients with moderate to severe kidney impairment	- Approved for long-term use in patients aged 6 years and above with genetically confirmed or suspected deficiency of POMC, PCSK1, or LEPR. - Inject subcutaneously in the abdomen, thigh, or upper arm rotating sites each day - Administer at the beginning of the day without regard to timing of meals
Noradrenergic Agents					
Phendimetrazine	Bontril® PDM; Bontril® Slow-Release	- Conventional tablet: start at 17.5 mg two or three times daily, given 1 hour before meals - Extended-release capsule: 105 mg	70-105 mg/day	Use caution in patients with kidney impairment	- Approved for short-term monotherapy - Controlled

		once daily 30-60 minutes before morning meal			substance: C–III • Prescriptions should be written for the smallest quantity to minimize possibility of overdose
Phentermine	• Lomaira™ • Adipex-P®	• 8 mg three times daily, given ½ hour before meal • Orally disintegrating tablet: 15 or 30 mg once every morning • Phentermine hydrochloride: 15-37.5 mg/day given in one or two divided doses; administer before breakfast or 1-2 hours after breakfast	• 8 mg three times daily, given ½ hour before meal • Orally disintegrating tablet: 15 or 30 mg once every morning • Phentermine hydrochloride: 15-37.5 mg/day given in one or two divided doses; administer before breakfast or 1-2 hours after breakfast	Use with caution in patients with kidney impairment	• Approved for short-term monotherapy • Controlled substance: C–IV • Prescriptions should be written for the smallest quantity to minimize possibility of overdose • Individualize to achieve adequate response with lowest effective dose
Diethylpropion	Tenuate®, Tenuate Dospan	• Immediate release: 25 mg three times daily administered 1 hour before meals • Controlled release: 75 mg once daily administered at midmorning	75 mg/day	Use with caution in patients with kidney impairment	• Approved for short-term monotherapy • Dose should not be administered in the evening or at bedtime • Controlled substance: C–IV

[a] Available without a prescription.

A multidisciplinary team approach to the management of obesity is necessary to ensure long-term success. It is common for patients to use a combination of nonprescription, prescription, and other complementary and alternative therapies to attain the desired weight loss goal. Therefore, clinicians should maintain a high degree of sensitivity toward the potential polypharmacy practices of patients with obesity. Finally, it is prudent to consider specific patient factors and characteristics along with the efficacy and safety profiles of individual therapies when determining if use of a pharmacologic intervention is warranted.

Agents Approved for Long-Term Use

8 There are currently six products approved in the United States for the chronic management of obesity. These include the lipase inhibitor orlistat (Xenical®, Genentech USA, South San Francisco, CA; Alli®, GlaxoSmithKline, Middlesex, UK), the combination product phentermine–topiramate extended release (Qsymia®, Vivus, Inc, Mountain View, CA), the combination product naltrexone-bupropion extended-release tablets (Contrave®, Takeda Pharmaceuticals America Inc, Cambridge, MA), the GLP-1 receptor agonists liraglutide (Saxenda®, Novo Nordisk Inc, Plainsboro, NJ) and semaglutide (Wegovy™, Novo Nordisk Inc, Plainsboro, NJ), and the melanocortin 4 (MC4) receptor agonist, setmelanotide (Imcivree™, Rhythm Pharmaceuticals Inc, Boston, MA). Pharmacotherapy management guidelines recommend discontinuation of medication therapy in patients who fail to lose sufficient amounts of body weight after 3 months and in patients who experience significant adverse medication reactions, with consideration given to potential alternative weight loss agents (strong recommendation with high-quality evidence).[29] Table 167-7 lists clinical and economic considerations for use of the products approved for long-term use.

TABLE 167-7

Clinical and Economic Considerations for Long-Term Pharmacotherapy Options

Medication	Brand Name	Weight Loss Above Diet and Exercise Alone (1 year)[85–88]	Cost for 30 Days of Therapy[a]	Comments
Orlistat	Xenical®	2.9-3.4 kg (6.5-7.5 lb)	$685.81	- Use may be limited by GI intolerance
Phentermine and topiramate extended release	Qsymia®	6.6-8.6 kg (14.5-18.9 lb)	• $186.00-7.5 mg- 46 mg • $199.50-15 mg-92 mg	- Limited distribution under FDA Risk Evaluation Mitigation Strategy (REMS)
Bupropion and naltrexone extended release	Contrave®	4.9 kg (10.8 lb)	$303.60	- Lowers seizure threshold (bupropion) - Rare reports of hepatotoxicity (naltrexone) - Drug interactions with opioids, CYP2B6 inducers and CYP2D6 substrates
Liraglutide	Saxenda®	5.2 kg (11.4 lb)	$1,349.00	- Injectable (daily dosing) - Available as pre-filled dosing pen - Reduces HbA1c and fasting glucose - Risk of medullary thyroid carcinoma and multiple endocrine neoplasia syndrome type 2 - Rare reports of pancreatitis, gallbladder disease, and suicidal ideation
Semaglutide	Wegovy™	15.5 kg (34.1 lb)[b]	$1,349.00	- Injectable (weekly dosing) - Available as pre-filled dosing pen - Reduces HbA1c and fasting glucose - Risk of medullary thyroid carcinoma and multiple endocrine neoplasia syndrome type 2 - Rare reports of pancreatitis, gallbladder disease, and suicidal ideation
Setmelanotide	Imcivree™	23.1% (patients with POMC or PCSK1 deficiency) 9.7% (patients with LEPR deficiency)	$19,800	- Injectable (daily dosing) - Available as multiple-dose vial (10 mg/mL) - Indicated for genetically confirmed or suspected deficiency POMC, PCSK1, or LEPR

[a]Cost of therapy based on maintenance dose using wholesaler acquisition cost (WAC) as of September 29, 2021.

[b]Data from 68-week trial

Lipase Inhibitor: Orlistat

Excessive intake of dietary fat is one of the contributing factors in the development of obesity. GI (gastric, pancreatic, and carboxyl ester) lipases are essential in the absorption of the long-chain triglycerides. Additionally, lipase is known to play a role in facilitating gastric emptying and secretion of other pancreaticobiliary substances. Orlistat (Xenical®) is a synthetic derivative of lipstatin, a natural lipase inhibitor produced by *Streptomyces toxytricini*. The medication is minimally absorbed and induces weight loss by persistent lowering of dietary fat absorption through selective inhibition of the GI lipase. Furthermore, lower luminal free fatty acid concentrations result in malabsorption of cholesterol. Up to 30% reduction in fat absorption occurs with daily doses of 120 mg three times daily with meals.[89] A nonprescription formulation of orlistat (Alli®) is approved in the United States at a reduced daily dose of 60 mg three times daily.[89] The medication must be taken within 1 hour of consuming foods that contain fat in order to exert its effect. If a meal is skipped or contains no fat, the dose of orlistat can be omitted.

As an adjunct to diet therapy, orlistat results in dose-dependent reductions in fat absorption. Orlistat modestly increases the amount of weight lost and decreases the amount of weight regained during medically supervised weight loss programs.[89] Improved glycemic control can be attained in patients with type 2 diabetes mellitus by inducing or increasing weight loss with orlistat in addition to diet management.[89] In some cases, dosages or the number of antidiabetic medications may be reduced or discontinued. Improvements in the lipid profile (reduction in total and low-density lipoprotein [LDL] cholesterol), glucose control, and other markers of metabolism are seen when using orlistat in addition to the diet.[89,90] Orlistat is approved for the chronic treatment of obesity in adults and adolescents between ages 12 and 16 years. The recommended dose is 120 mg three times daily taken within 1 hour of consuming a fat-containing meal.

At least one GI complaint (soft stools, abdominal pain or colic, flatulence, fecal urgency, or incontinence) has been reported in up to 80% of individuals using prescription-strength orlistat. These complaints are most common in the first 1 to 2 months of therapy, are mild to moderate in severity, and tend to improve with continued orlistat use. Limiting dietary fat before initiation of orlistat therapy may be beneficial in decreasing initial GI complaints. Severe diarrhea secondary to orlistat use can affect the absorption of orally administered medications, such as oral contraceptives, fat-soluble vitamins (A, D, E, and K), and β-carotene. Therefore, supplementation with a multivitamin should be considered during therapy. In the presence of severe diarrhea, women receiving oral contraceptives should be advised of the need to use alternative backup methods because absorption of oral contraceptive may be reduced. Reduced fat absorption can potentially affect the absorption of lipophilic medications, such as lamotrigine, valproic acid, gabapentin, and amiodarone.[91,92] Decreased vitamin K absorption has also been noted and can alter the patient's warfarin dosage needs. Clinicians should also be aware that orlistat may directly interfere with the absorption of other narrow therapeutic range medications, such as cyclosporine, levothyroxine, and antiretrovirals.[92] In patients requiring concomitant therapies with orlistat, close monitoring is warranted to ensure an adequate therapeutic response. Separation of the administration times of the medications may minimize these potential drug interactions. Finally, there have been rare postmarketing reports of liver damage with the use of orlistat.[92] Although causality has not been definitively linked to orlistat, patients are advised to notify their healthcare providers if they notice signs and symptoms of liver injury, such as development of itching, yellow eyes or skin, dark urine, loss of appetite, or light-colored stools.

Phentermine–Topiramate Extended Release

A combination product containing phentermine and topiramate extended release (Qsymia®) is approved for chronic weight management in patients who have obesity (BMI of greater than or equal to 30 kg/m^2) or overweight (BMI of greater than 27 kg/m^2) with at least one weight-related comorbidity.[93] Phentermine is structurally similar to amphetamine, but it has less severe CNS stimulation and a lower misuse potential. Its mechanism of action centers on its ability to enhance norepinephrine (NE) and dopamine neurotransmission, resulting in appetite suppressing effects. Topiramate is an antiseizure medication. Although the exact mechanism for its efficacy in weight management is unknown, it may decrease appetite and increase satiety through multiple pathways, including effects on γ-aminobutyrate, voltage-gated ion channels, excitatory glutamate receptors, or carbonic anhydrase.[93] The doses of phentermine (3.75-15 mg) and topiramate (23-92 mg) in this combination are lower than the therapeutic doses of each separate product when used as monotherapy for obesity (37.5 mg) and seizures (400 mg), respectively. The recommended dosing strategy for phentermine–topiramate extended release involves gradual titration, staring with 3.75 mg of phentermine and 23 mg of topiramate once daily for 14 days and then increasing the dose to 7.5 mg of phentermine and 46 mg of topiramate once daily.[93] After 12 weeks of therapy, the dose may be increased again to 11.25 mg of phentermine and 69 mg of topiramate for 14 days and then to a maximum dose of 15 mg of phentermine and 92 mg of topiramate daily. Likewise, when discontinuing therapy, the dose should be gradually decreased by taking a dose every other day for at least 1 week to prevent the possible precipitation of seizures.

When used as an adjunct to a reduced-calorie diet and lifestyle changes, phentermine–topiramate leads to dose-dependent weight loss and reductions in blood pressure, total cholesterol, LDL cholesterol, triglycerides, fasting glucose, and HbA_{1c}.[85] Mean weight loss after 1 year of treatment is 8.1 kg (17.8 lb) for the 7.5-mg phentermine and 46-mg topiramate dose and 10.2 kg (22.4 lb) for the 15-mg phentermine and 92-mg topiramate group. The efficacy of phentermine–topiramate has also been documented in patients with class II and class III obesity (mean BMI, 42 kg/m^2), with a mean weight loss of 10.9% after 1 year of treatment.[85]

The most common adverse medication reactions associated with the use of phentermine–topiramate are constipation, dry mouth, paraesthesia, dysgeusia, and insomnia.[85,93] Because topiramate is a known teratogen, this medication is contraindicated in pregnancy because fetal exposure in the first trimester increases the risk of cleft lip or cleft palate. To manage the potential risk of teratogenicity, the medication is only available through a limited distribution process under a risk evaluation and mitigation strategy (REMS).[93] All women of childbearing age must have a documented negative pregnancy test result before beginning treatment and then monthly to continue therapy. Topiramate has been associated with acute myopia associated with secondary angle-closure glaucoma, and phentermine can cause mydriasis from adrenergic stimulation. Therefore, this product is also contraindicated in patients with glaucoma. The potential for hypertensive crisis with coadministration of phentermine and monoamine oxidase inhibitors (MAOIs) exists; therefore, patients should have stopped an MAOI for at least 14 days before use of any adrenergic agent. Phentermine–topiramate is also contraindicated in patients with untreated hyperthyroidism.

Monitoring parameters and drug interactions that clinicians should be aware of include known issues related to both components of the formulation. Of note, increases in heart rate greater than 10 beats/min are observed in approximately 50% of patients receiving phentermine–topiramate.[93] In patients receiving the highest dose, 19% experience increases in heart rate that are greater than 20 beats/min. Therefore, heart rate should be monitored in all patients, particularly those with preexisting CVD. Decreases in serum bicarbonate are generally mild, but peak after 4 weeks of therapy. Decreases in serum potassium and increases in serum creatinine are also seen. Therefore, monitoring of serum electrolytes and creatinine is recommended at baseline and during therapy. Clinicians should be aware that concomitant use of non–potassium-sparing diuretics may potentiate the risk for hypokalemia. Although pregnancy risk is not expected, use of phentermine–topiramate concomitantly with oral contraceptives may result in breakthrough bleeding because of increased exposure to progestin and decreases exposure to estrogen. Phentermine–topiramate is classified as a controlled substance in schedule IV because of the misuse potential of phentermine. Therapy should be discontinued if 5% weight loss is not achieved after 12 weeks with the 7.5-mg phentermine and 46-mg topiramate dose.[93]

Naltrexone–Bupropion Extended Release

A combination product containing naltrexone and bupropion extended release (Contrave®) is approved for chronic weight management in patients who have obesity (BMI of more than or equal to 30 kg/m^2) or overweight (of more than or equal to 27 kg/m^2) with at least one weight-related comorbidity.[94] Naltrexone and bupropion are both approved separately for treatment of alcohol and opioid physical dependence, and depression and smoking cessation, respectively.[95] Bupropion is a dopamine and norepinephrine reuptake inhibitor, and naltrexone is an opioid antagonist. Although the exact weight-loss mechanism of action is not known for this medication combination, stimulation of release of α-MSH in hypothalamus by bupropion and inhibition of endogenous opioids by naltrexone are thought to contribute to a decrease in appetite.[95] The recommended dosing strategy for naltrexone-bupropion extended-release involves gradual titration, starting with one tablet (8-mg naltrexone/90-mg bupropion) per day and slowly increasing the dose over a period of 4 weeks to a maintenance dose of two tablets twice daily. Doses greater than 32 mg of naltrexone and 360 mg of bupropion (ie, 4 tablets) per day are not recommended. Patients should be advised to not take their dose with a high-fat meal as this would result in increased systemic exposure to both naltrexone and bupropion.

When used in combination with a reduced-calorie diet and lifestyle changes, naltrexone/bupropion is associated with improvements in high-density lipoprotein (HDL) cholesterol, triglycerides, glucose, and insulin.[85,95] Average total weight loss is 7.3 kg (16.1 lb) following one year of treatment,[95] with the greatest weight loss (9.7 kg [21.3 lb]) seen in patients without diabetes mellitus also receiving intensive behavior modification therapy.[85]

The most common adverse medication reactions associated with the use of naltrexone/bupropion are nausea, constipation, headache, vomiting, dizziness, insomnia, dry mouth, and diarrhea.[94] Approximately 24% of patients who receive naltrexone-bupropion discontinue treatment due to adverse medication reactions, with nausea being the most frequent reason.[94] Statistically significant increases in heart rate (2.1 beats/min) and blood pressure (1.8-2.3 mm Hg systolic and 1.7-2.1 mm Hg diastolic) occur in patients receiving naltrexone-bupropion during the first 3 months of therapy, but the clinical significance of these increases is unknown. Blood pressure and pulse should be monitored at baseline and at regular intervals following initiation of therapy. Naltrexone-bupropion should not be used in patients with uncontrolled hypertension.[94] Naltrexone monotherapy is associated with rare reports of hepatotoxicity, and patients receiving naltrexone-bupropion should be advised of the signs and symptoms of acute hepatitis. Bupropion lowers the seizure threshold in a dose-dependent manner and has been associated with serious neuropsychiatric reactions and an increased risk of suicidal thoughts and behavior when used for smoking cessation and treatment of depression. Bupropion may also be associated with activation of mania, serious allergic reaction, and angle-closure glaucoma.

Clinicians should also be aware of potential drug interactions with naltrexone-bupropion. Because of the opioid antagonist effects of naltrexone, naltrexone-bupropion is contraindicated in patients receiving chronic opioid or opiate agonist therapy, and also in patients undergoing abrupt withdrawal of chronic alcohol, benzodiazepine, barbiturate or antiseizure medications. Bupropion is metabolized by cytochrome P450 2B6 (CYP2B6) and inhibits cytochrome P450 2D6 (CYP2D6). Therefore, any medication that induces CYP2B6 (eg, rifampin, carbamazepine) could potentially reduce the effects of bupropion, and bupropion could increase the effects of medications that are CYP2D6 substrates (eg, SSRIs, tricyclic antidepressants, antipsychotics). Bupropion is also contraindicated with concomitant use of MAOIs. As with other long-term pharmacologic treatments for obesity, weight loss may increase the risk of hypoglycemia in patients with type 2 diabetes mellitus receiving antidiabetic medications. Finally, treatment with naltrexone-bupropion should be discontinued if 5% weight loss is not achieved after 12 weeks.[94]

Glucagon-Like Peptide-1 Receptor Agonists

Liraglutide

Liraglutide (Saxenda®), an analog of GLP-1, is approved in the United States for chronic weight management in adult patients who have obesity (BMI of more than or equal to 30 kg/m^2) or overweight (BMI of more than 27 kg/m^2) with at least one weight-related comorbidity and in adolescents age 12 years and older with body weight above 60 kg (132 lb) and an initial BMI corresponding to obesity according to international cut-offs for age and sex.[96] Endogenous GLP-1 is released in response to food digestion and stimulates GLP-1 receptors in the brain to reduce appetite. GLP-1 also stimulates insulin secretion and reduces glucagon secretion. For that reason, several GLP-1 receptor agonists, including liraglutide, are currently approved for the treatment of type 2 diabetes mellitus at recommended doses of 1.2 mg or 1.8 mg daily far less than the maintenance dose for weight loss of 3 mg daily. Liraglutide is administered subcutaneously and is available in prefilled, multidose pens. When used for weight loss, a 5-week dose escalation schedule is recommended to improve tolerability of GI adverse medication reactions. It should be initiated at a dose of 0.6 mg daily, and increased weekly by 0.6-mg increments to a final maintenance dose of 3 mg daily. If the patient cannot tolerate the GI adverse medication reactions at any point during the dose escalation phase, a dose increase may be delayed by a week. Patients should be instructed on the proper technique for subcutaneous injection into the abdomen, thigh, or upper arm.

The efficacy of liraglutide for the management of overweight and obesity has been studied in patients with and without diabetes mellitus. A mean weight loss of 5.2 kg (11.4 lb) more than placebo is observed after 1 year of treatment with liraglutide;[86] slightly less weight loss is reported for adolescents.[97] As expected, patients who receive liraglutide also experience improvements in HbA$_{1c}$, fasting glucose and insulin, and had a lower prevalence of prediabetes. Similarly, patients with diabetes mellitus experience a 6% average weight loss after 1 year of treatment.[93] Improvements in fasting glucose and the number of subjects achieving HbA$_{1c}$ targets are also observed. The most common adverse medication reactions associated with the use of liraglutide are nausea, diarrhea, constipation, vomiting, dyspepsia, hypoglycemia, and abdominal pain.[96] GI complaints are the most common reason for premature discontinuation of therapy, underscoring the importance of the slow dose-escalation schedule with initiation of therapy. Rare cases of acute pancreatitis (0.3%), potentially leading to fatal hemorrhagic or necrotizing pancreatitis, may occur with the use of liraglutide.[93] Resting heart rate increases an average of 2 to 3 beats/min with liraglutide; however, increases as high as 20 beats/min may be seen. Although the clinical significance of these increases is unknown, heart rate should be regularly monitored in all patients receiving liraglutide. Cholelithiasis (1.5%), cholecystitis (0.6%), and suicidal ideation (0.2%) are also observed.[96] Liraglutide carries a boxed-warning about the risk of thyroid C-cell tumors, including medullary thyroid carcinoma (MTC), and is contraindicated in patients with a personal or family history of MTC or multiple endocrine neoplasia syndrome type 2 (MEN2). Hypoglycemia may occur when liraglutide is used in combination with other antidiabetic agents (particularly sulfonylureas and insulin) in patients with type 2 diabetes mellitus. Therefore, dose adjustments of antidiabetic medications may be necessary. Because liraglutide increases gastric emptying time, clinicians also should be aware that absorption of concomitantly administered oral medications may be altered. Liraglutide should be discontinued if weight loss of at least 4% is not achieved after 16 weeks of therapy.

Semaglutide

Semaglutide (Wegovy™) is the most recent medication approved in the United States for chronic weight management in patients who have obesity (BMI of more than or equal to 30 kg/m^2) or overweight (BMI of more than 27 kg/m^2) with at least one weight-related comorbidity.[98] Similar to liraglutide, semaglutide stimulates GLP-1 receptors in the brain to reduce appetite. Semaglutide (Ozempic®) is also approved for the treatment of type 2 diabetes mellitus and to reduce the risk of major cardiovascular events in adults with type 2 diabetes mellitus and cardiovascular disease as a subcutaneous injection at a dose of 1 mg once weekly.[99] When used for weight loss, the starting of semaglutide is 0.25 mg once weekly for four weeks, followed by monthly dose escalation to improve tolerability of GI adverse medication reactions, to a maintenance dose of 2.4 mg weekly. If the patient cannot tolerate the GI adverse medication reactions at any point during the dose escalation phase, a dose increase may be delayed by a month. If a patient cannot tolerate the 2.4 mg weekly dose, the dose may be decreased to 1.7 mg weekly for one month before increasing the dose back to 2.4 mg weekly. Patients should be instructed on the proper technique for subcutaneous injection into the abdomen, thigh, or upper arm.

The efficacy of semaglutide for the management of overweight and obesity has been studied in patients with and without diabetes mellitus and has been associated with the greatest amount of weight loss when compared to all other approved weight loss medications.[87,100] Patients receiving semaglutide 2.4 mg weekly lose an average of 14.9% of their original body weight (15.5 kg [34.1 lb]) after 68 weeks of treatment and experience considerable improvements in systolic blood pressure, LDL cholesterol, and HbA1C measurements.[87] Notably, 50% of subjects receiving semaglutide achieve > 15% reduction in body weight. In patients with type 2 diabetes mellitus, average weight loss is 9.6% after 68 weeks of therapy.[100]

Adverse medication reactions associated with the use semaglutide are similar to those observed with liraglutide and include nausea, diarrhea, constipation, vomiting, dyspepsia, and abdominal pain.[87,98,100] Semaglutide is also associated with rare cases of acute pancreatitis, acute gall bladder disease, acute kidney injury, diabetic retinopathy, and small increases in resting heart rate.[98] Semaglutide carries a boxed-warning about the risk of thyroid C-cell tumors, including MTC, and is contraindicated in patients with a personal or family history of MTC or multiple endocrine neoplasia syndrome type 2 (MEN2). As with liraglutide, hypoglycemia may occur when semaglutide is used in combination with other antidiabetic agents in patients with type 2 diabetes mellitus. Therefore, dose adjustments of antidiabetic medications may be necessary.

Melanocortin 4 (MC4) Receptor Agonist

Setmelanotide

Setmelanotide (Imcivree™) is a peptide analog of endogenous alpha-melanocyte stimulating hormone (α-MSH) approved for chronic weight management in patients with genetically confirmed or suspected proopiomelanocortin (POMC), proprotein convertase subtilisin/kexin type 1 (PCSK1) or leptin receptor (LEPR) deficiency.[101] Patients with variants in POMC, PCSK1, or LEPR genes are thought to have obesity due to insufficient activation of MC4 receptors in the brain. Setmelanotide is an MC4 receptor agonist that results in reduced hunger and promotes weight loss through decreased energy intake and slightly increased energy expenditure. Setmelanotide is indicated in adults and children aged 6 years and older. It is administered once daily as a subcutaneous injection with a starting dose of 2 mg daily for those 12 years and older and 1 mg daily for children aged 6 to less than 12 years.[101] Depending on tolerability the dose can be gradually increased to a maximum of 3 mg daily. In patients with LEPR or POMC deficiency, setmelanotide is associated with > 10% weight loss after one year of treatment in 45% and 80% of subjects, respectively.[88] The most common adverse medication reactions associated with setmelanotide include injection site reactions (96%), skin hyperpigmentation (78%), nausea (56%), headache (41%), diarrhea (37%), and abdominal pain (33%).[101] Sexual adverse medication reactions such as spontaneous penile erections may occur. Male patients should be advised to seek medical treatment for an erection lasting longer than 4 hours. It is also advised to monitor for the potential of new or worsening depression and suicidal ideation. According to the manufacturer, if a patient fails to lose at least 5% of baseline body weight (or 5% of baseline BMI) after 12 to 16 weeks of treatment, it is recommended to discontinue setmelanotide due to a low potential for a meaningful weight loss with continued treatment.[101]

Agents Approved for Short-Term Use

Several noradrenergic agents are currently approved by the FDA for short-term weight loss. Because short-term therapy is not consistent with current national guidelines for the chronic management of obesity, these agents have limited clinical utility in practice.[6,7]

Phentermine

Phentermine is available in both immediate-release and sustained-release formulations. However, the value of sustained-release formulations is questionable based on the phentermine plasma half-life of 12 to 24 hours. Phentermine is an effective adjunct to diet, exercise, and behavior modification for producing weight loss.[102] Intermittent phentermine therapy appears to elicit comparable weight loss as that seen with continuous use. However, most individuals experience weight regains during therapy and generally always after discontinuing use.[102] A single dose of 30 mg once daily in the morning provides effective appetite suppression throughout the day. Divided doses of 8 mg immediately before meals, however, are common.[103] Evening or nighttime dosing should be avoided because of insomnia. Large increases in blood pressure, palpitations, and arrhythmias can occur with phentermine administration. Use is not advisable in hypertensive patients. Pharmacotherapy management guidelines recommend against the use of sympathomimetic agents in patients with uncontrolled hypertension or a history of CVD (strong recommendation with high-quality evidence).[29]

The potential for hypertensive crisis with coadministration of phentermine and MAOIs is noted in the product labeling of each agent; therefore, patients should be off an MAOI for at least 14 days before use of any adrenergic agent to avoid excessive adrenergic stimulation syndromes.[104] Phentermine use is contraindicated in patients with hyperthyroidism or agitated states and in those who misuse substances such as cocaine, phencyclidine, and methamphetamine, again because of the potential for excessive adrenergic stimulation syndromes and misuse potential. Mydriasis from adrenergic stimulation can worsen glaucoma, and patients diagnosed with glaucoma should not receive phentermine. Patients with diabetes mellitus may experience altered insulin or oral hypoglycemic dosage requirements soon after beginning therapy and before any substantial weight loss. Phentermine remains the most widely prescribed weight management medication by obesity specialists despite product labeling that indicates short-term (a few weeks), monotherapy use only.[102] This usage pattern deviates from the current national recommendations that promote only long-term medication intervention when obesity pharmacotherapy is appropriate.[7] Some clinicians consider use of long-term phentermine to be reasonable in select patients given the low cost and a lack of serious long-term adverse medication reactions reported over the past 20 years. Select patients include those without CVD, psychiatric disease, or substance misuse; without clinically significant increases in blood pressure or heart rate while receiving phentermine; and documentation of weight loss while receiving phentermine.

Diethylpropion

Diethylpropion stimulates NE release from presynaptic storage granules. Increased adrenergic neurotransmitter concentrations activate hypothalamic centers, which result in decreased appetite and food intake. Diethylpropion can be taken in divided daily doses, generally 25 mg three times daily before meals. An extended-release formulation is also used by some clinicians, usually as 75 mg taken once daily in the morning or midmorning.[102] Both dosing regimens are effective in achieving short-term weight loss. Complaints of insomnia increase if late afternoon dosing is used. Diethylpropion causes less stimulation of the CNS than mazindol and generally causes less insomnia than phentermine. Patients with severe hypertension or CVD should not receive diethylpropion. Patients with diabetes mellitus may experience decreased insulin or oral hypoglycemic dosage requirements soon after beginning therapy and before any substantial weight loss. In patients with diabetes mellitus, more frequent blood glucose self-monitoring and medical follow-up are warranted when treating patients with diethylpropion.

Amphetamines

Appetite suppressant effects of the amphetamines were well recognized in the 1930s. Amphetamines activate central noradrenergic receptor systems as well as dopaminergic pathways at higher doses by stimulating neurotransmitter release. Increases in blood pressure and mild bronchodilation are attributed to peripheral α- and β-receptor activation. Amphetamines are no longer widely used for the treatment of obesity because of their powerful stimulant effects and addictive potential.

Complementary and Alternative Therapies

⑨ Many complementary and alternative therapy products are currently promoted for weight loss. A nationwide survey of US consumers reported that about 15.2% of adults had used “dietary supplements” specifically for the purposes of weight loss.[105] It is important for clinicians to be aware that the regulation of dietary supplements is less rigorous than that of prescription and over-the-counter medications. As such, a manufacturer of a dietary supplement does not have to prove the safety or effectiveness of the product before it is marketed. Of concern, some herbal and food supplement diet agents contain pharmacologically active substances that should be used with caution or avoided in patients who have obesity who also have conditions such as diabetes mellitus, hypertension, and CVD. In addition, many marketed products lack consistency in labeling versus actual product content, and a number of dietary supplements have been found to contain undeclared prescription medications. Common herbal and natural products that have been used for weight loss include hoodia, green tea, citrus aurantium, forskolin, caffeine, glucomannan, yohimbine, chitosan, guar gum, hydroxycitric acid, and garcinia cambogia.[105,106]

EVALUATION OF THERAPEUTIC OUTCOMES

The evaluation and management of a patient with obesity requires careful clinical; biochemical; and, if necessary, psychological evaluation. This evaluation should include an assessment of the patient's current medical condition and medication regimen. A multidisciplinary team including, but not limited to, a physician, dietitian, psychologist, behavioral expert, and pharmacist should ideally be involved in the care of individuals with obesity.

Monitoring the Pharmaceutical Care Plan

Assessment of patient progress should be documented frequently.[6] Each encounter should document weight, WC, BMI, blood pressure, medical history, and patient assessment of obesity medication tolerability.[6] Chronic use of obesity medications should be consistent with the approved product labeling. According to current pharmacologic management guidelines, efficacy, and tolerability of the medication should be assessed monthly for the first 3 months, followed by visits every 3 months thereafter (weak recommendation with low quality evidence).[29] If the patient has failed to demonstrate weight loss or maintenance of prior weight, medication therapy should be discontinued after 3 months (strong recommendation with high quality evidence).[29]

To achieve optimal weight loss, patients should be instructed about the importance of adherence to prescribed medication and lifestyle changes. The Short Form 36 (SF-36) is used as a quality-of-life evaluation tool for patients with obesity undergoing programmatic weight loss. Quarterly assessments of well-being and quality of life using validated assessment tools can be helpful in objectively quantifying the effectiveness of therapy. Table 167-8 provides monitoring parameters and potential adverse medication reactions of agents used for long-term management of overweight and obesity.

TABLE 167-8

Adverse Medication Reactions and Monitoring Parameters

Medication	Brand Name	Adverse Medication Reactions	Monitoring Parameters	Comments
Gastrointestinal Lipase Inhibitor				
Orlistat	Xenical®, Alli® [a]	Soft stools, diarrhea, abdominal pain or colic, flatulence, fecal urgency, incontinence, liver damage (rare)	BMI; calorie and fat intake; serum glucose in patients with diabetes; thyroid function in patients with thyroid disease; liver function tests in patients exhibiting symptoms of hepatic dysfunction	Supplement with a multivitamin during therapy to prevent vitamin deficiency
Phentermine–Topiramate Combination				
Phentermine and topiramate extended release	Qsymia®	Constipation, dry mouth, paresthesia, dysgeusia, insomnia, hypoglycemia in patients with diabetes	BMI; calorie and fat intake; serum glucose in patients with diabetes; pregnancy; depression or suicidal thoughts; mood or sleep disorders; heart rate; serum electrolytes and creatinine at baseline and during treatment	• Discontinue or escalate dose if 3% weight loss not achieved by week 12 on phentermine 7.5 mg and topiramate 46 mg • Discontinue if 5% weight loss not achieved by

				week 12 on phentermine 15 mg and topiramate 92 mg - Gradually discontinue phentermine 15 mg and topiramate 92 mg to prevent possible seizure
Bupropion-Naltrexone Combination				
Bupropion and naltrexone extended release	Contrave®	Nausea, constipation, headache, vomiting, dizziness, insomnia, dry mouth and diarrhea	BMI; calorie and fat intake; serum glucose in patients with diabetes; heart rate and blood pressure; signs and symptoms of hepatotoxicity, neuropsychiatric reactions, and suicidal thoughts or behavior	Discontinue if 5% weight loss not achieved by week 12
Glucagon-Like Peptide-1 Antagonists				
- Liraglutide - Semaglutide	- Saxenda® - Wegovi™	Nausea, diarrhea, constipation, vomiting, dyspepsia, hypoglycemia, and abdominal pain	BMI; calorie and fat intake; serum glucose in patients with diabetes; signs and symptoms of pancreatitis; heart rate; signs and symptoms of gallbladder disease and suicidal ideation	Discontinue liraglutide if 4% weight loss not achieved by week 16. At present, there is no recommendation to discontinue semaglutide therapy for inadequate weight loss at week 16.
Melanocortin 4 Receptor Agonist				
Setmelanotide	**Imcivree™**	Injection site reactions, skin hyperpigmentation, nausea, headache, diarrhea, and abdominal pain	BMI; calorie and fat intake; serum glucose in patients with diabetes, sexual adverse medication reactions, new or worsening depression, and suicidal ideation	- Approved for patients with genetically confirmed or suspected deficiency of POMC, PCSK1, or LEPR - Discontinue if 5% weight loss (or 5% decrease in BMI) not achieved after 12 to 16 weeks
Noradrenergic Agents				
- Phendimetrazine - Phentermine - Diethylpropion	- Bontril® PDM; Bontril® Slow-Release - Adipex-P®, Suprenza™	Increased blood pressure, ischemic events, palpitations, tachycardia, valvular disease, urticaria, agitation, dizziness, headache, insomnia, overstimulation, psychosis, restlessness, dry mouth, constipation, thirst, diarrhea	Baseline cardiac evaluation (for preexisting valvular heart disease, pulmonary hypertension); echocardiogram during therapy; weight, waist circumference; blood pressure	- Approved as monotherapies only for short-term use (a few weeks). - Discontinue if satisfactory weight loss has not occurred within the first 4 weeks of

	- Tenuate®, Tenuate Dospan			treatment or if tolerance develops - Abrupt discontinuation after prolonged high doses may be associated with extreme fatigue and depression

BMI, body mass index.

[a]Available without a prescription.

Patients with diabetes mellitus receiving weight loss medication require more intense medical monitoring and self-monitoring of blood glucose to minimize the risk for hypoglycemia. Insulin therapy may need to be reduced with the start of obesity medication therapy. Some patients with diabetes mellitus may require daily telephone contact with a healthcare provider to assist in adjusting their hypoglycemic therapy. Weekly patient visits to a healthcare setting may be necessary for 1 to 2 months until the effects of diet, exercise, and weight loss medication become more predictable. As frequent as quarterly assessment of HbA_{1c} may be appropriate in patients with type 2 diabetes mellitus who lose weight to aid in adjustment of hypoglycemic therapy. Lipid profiles can normalize or improve with weight loss. Lipid status should be assessed semiannually or annually in patients with hyperlipidemia to determine the need for continued hyperlipidemia therapies. Weight loss also can result in normalization of blood pressure in hypertensive patients who have obesity. Assessment of appropriateness of antihypertensive therapy should occur with each follow-up visit.

CONCLUSION

Obesity is a complex chronic disease with a prevalence that has increased dramatically over the past 50 years. Increased body weight is a consequence of increased energy storage resulting from an imbalance between energy intake and energy expenditure over time, which is influenced by many factors, including genetics and the environment. Nonpharmacologic therapy, including reduced caloric intake, increased physical activity, and behavioral modification, is currently the mainstay of obesity management. Medication therapy may be considered as an adjunct for patients who fail to achieve adequate weight loss with comprehensive lifestyle modifications. Currently, six products—orlistat, phentermine–topiramate extended release, naltrexone-bupropion extended release, liraglutide, semaglutide, and setmelanotide—are approved by the FDA for the long-term treatment of overweight and obesity. Bariatric procedures have long-term efficacy for weight reduction, but they also introduce surgical comorbidities and, for the most efficacious procedures, may cause nutritional deficiencies. For patients who are not able to undergo bariatric surgery, medical devices may also be considered. Treatment of obesity should be individualized, considering factors such as patient desires, age, degree and duration of obesity, and the presence and severity of medical conditions both directly related to obesity and those that may have an impact on the therapeutic decisions. Regardless of the chosen treatment plan, the management of obesity is a lifelong process requiring patient support and careful monitoring for safety and efficacy.

ABBREVIATIONS

5-HT	5-hydroxytryptamine (serotonin)

SELF-ASSESSMENT QUESTIONS

1. According to the National Institutes of Health (NIH) guideline, which category *best* describes a 45-year-old Hispanic male who is 5 ft 11 in. (180 cm) tall and weighs 302 lb (135 kg)?

   A. Normal weight

   B. Overweight

   C. Obesity

   D. Extreme obesity

2. Which one of the following is the *best* management approach after determining a patient needs to lose weight?

   A. Prescribe a FDA-approved pharmacotherapy to lose weight

   B. Assess the patient’s readiness to lose weight

   C. Refer to a high-intensity comprehensive lifestyle intervention program to lose weight

   D. Set a weight lose goal of 10% weight loss over the next month

3. The Look Action for Health in Diabetes (AHEAD) study found that patients with diabetes mellitus who maintained weight loss of at least 7% with intensive lifestyle modifications for almost 10 years were able to demonstrate which of the following?

A. Did not experience an increased incidence of cardiovascular events, but they did have an increased need for diabetes mellitus medications and improvement in physical function

B. Did not experience a reduced incidence of cardiovascular events, but they did have an increased need for diabetes mellitus medications and improvement in physical function

C. Did not experience a reduced incidence of cardiovascular events, but they did have a reduced need for diabetes mellitus medications and improvement in physical function

D. Experienced an increased incidence of cardiovascular events, but they did have a reduced need for diabetes medications an improvement in physical function

4. Which one of the following weight loss goals is recommended for a White female with BMI of 32 kg/m^2 who also has type 2 diabetes mellitus requiring weight-loss intervention?

A. 5%

B. 7% to 8%

C. 5% to 15% or more

D. Uncertain

5. Which one of the following interventions represents the mainstay of weight loss therapy?

A. Conventional Roux-en-Y gastric bypass

B. Neurometabolic therapy

C. Locaserin 10 mg orally twice daily

D. Reduced-calorie diet, exercise, and behavioral modification

6. A 35-year-old White female weighs 163 lbs (74 kg), height of 5’4” (163 cm) with BMI of 28 kg/m^2. She is interested in losing weight in the next few months so she can wear summer clothes comfortably. She has uncontrolled hypertension and polycystic ovary syndrome. Which of the following is the *most appropriate* weight-loss recommendation for this patient?

A. Lifestyle modification only

B. Weight-loss medication and lifestyle modifications

C. AspireAssist and lifestyle modifications

D. Bariatric surgery and lifestyle modifications

7. Which BMI classification *does not* meet the appropriate criteria for consideration of metabolic and bariatric surgery?

A. Extreme obesity with BMI ≥ 40 kg/m^2

B. Obesity with BMI ≥ 35 kg/m^2 with obstructive sleep apnea

C. Obesity with BMI between 30 and 34.9 kg/m^2 with diabetes or metabolic syndrome

D. Obesity with BMI between 30 and 34.9 kg/m^2 after failed diet and exercise without metabolic abnormalities

8. All of the following supplements are required to prevent nutritional deficiencies in metabolic and bariatric surgery patients, *except*:

A. Niacin

B. Iron

C. Vitamin B_{12}

D. Multivitamin

9. Which of the following postoperative considerations is important in patients after bariatric surgery?

A. Altered nutrient absorption

B. Altered medication absorption

C. Increased adverse medication reactions

D. All of the above

10. Bariatric surgery has been demonstrated to reduce the following obesity-related problems, *except*:

A. Cardiovascular death

B. Type 2 diabetes mellitus

C. Cancer

D. Crohn's disease

11. Acceptable weight management option for a 40-year-old obese woman with uncontrolled hypertension include all of the following, *except*:

A. Liraglutide

B. Lorcaserin

C. Phentermine

D. Orlistat

12. Which effect would *most likely* be experienced by a patient taking semaglutide?

A. Paraesthesia

B. Nausea

C. Headache

D. Dysgeusia

13. Pharmacotherapy with liraglutide should be discontinued if a patient fails to lose 4% of their initial body weight after:

A. 8 weeks

B. 12 weeks

C. 16 weeks

D. 20 weeks

14. Which effect would *most likely* be experienced by a patient taking phentermine/topiramate extended release?

    A. Increased heart rate

    B. Dumping syndrome

    C. Headache

    D. Priapism

15. All of the following antidiabetic medications promote weight loss, *except*:

    A. Metformin

    B. Glucagon-like peptide-1 analogs (GLP-1)

    C. Dipeptidyl peptidase-4 inhibitors (DPP-4)

    D. Sodium-Glucose-linked transporter-2 inhibitors (SGLT2)

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** The calculated BMI is 42 kg/m^2 for this patient. Using pounds and inches, BMI (kg/m^2) is estimated as (weight [lb]/height [inches^2]) × 703. A BMI of 18.5 to 24.9 kg/m^2 is considered underweight. Adults with a BMI of 25 to 29.9 kg/m^2 are considered “overweight”; the terms obese, and extreme obese are reserved for those with a BMI of 30 to 39.9 kg/m^2, and 40 kg/m^2 and over, respectively (see Table 167-3).

2. **B.** Once the need for weight loss has been determined, the clinician needs to assess a patient’s readiness to engage in weight loss efforts and identify any potential barriers to success before recommending any interventions. They need to initiate a dialogue with each patient who is overweight or obese to ensure they understand the potential health consequences of excess body weight and benefits of appropriate weight management. Specific weight goals should be established that are consistent with medical needs and the patient’s personal desire (see Table 167-4).

3. **C.** The Look Action for Health in Diabetes (AHEAD) study found that patients with diabetes who maintained weight loss of at least 7% with intensive lifestyle modifications for almost 10 years did not experience a reduced incidence of cardiovascular events, but they did have a reduced need for diabetes mellitus medications and improvement in physical function and other health benefits.

4. **C.** According to the AACE/ACE Guidelines, the recommended weight loss goal for adult with type 2 diabetes mellitus is 5% to 15% or more with the clinical goal of reducing A1c, reduce number and/or doses of glucose-lowering medications, and improve control of diabetes mellitus (see Table 167-4).

5. **D.** All successful obesity treatment plans require incorporation of comprehensive lifestyle interventions such as healthy diet, adequate physical activity, and behavioral modifications as the cornerstone of weight management.

6. **B.** According to current AACE/ACE guidelines, this patient is currently in obesity Stage 1, tertiary chronic disease phase of prevention based on the presence of one or more mild to moderate weight-related complications, therefore, weight-loss medications is to be initiated concurrently with lifestyle therapy with BMI ≥ 27 kg/m^2.

7. **D.** Bariatric surgery is recommended to individuals with extreme obesity (BMI ≥ 40 kg/m^2) or BMI at 35 kg/m^2 or above with at least one or more major comorbidity such as hypertension, type 2 diabetes mellitus, or obstructive sleep apnea. Surgery may also be advocated to patients with BMI between 30 and 34.9 kg/m^2 with diabetes mellitus or metabolic syndrome as it has a similar efficacy and safety profile for improving type 2 diabetes and metabolic disorders among bariatric patients with a BMI below or above 35 kg/m^2. Patients with BMI between 30 and 34.9 kg/m^2 and failed lifestyle modification would be recommended with pharmacologic weight loss therapy as the next step.

8. **A.** Due to the disruption of the normal gastric anatomy and physiology, postsurgical patients are often at risk for severe micronutrient deficiencies

(eg, vitamin B_{12}, vitamin B_1, vitamin K, zinc, copper, folate, iron, calcium) as well as deficiencies in fat soluble vitamins such as vitamins A, D, E, and K due to fat malabsorption. Therefore, empiric supplementation with daily adult multivitamin plus minerals, elemental calcium, vitamin D, folic acid, thiamine, elemental iron, and vitamin B_{12} is essential to prevent nutritional deficiencies in bariatric patients. The level of niacin is usually not affected after bariatric surgery.

9. **D.** Postoperative bariatric surgery patients are often at risk for severe micronutrient deficiencies such as vitamin B_{12}, vitamin B_1, vitamin K, zinc, copper, folate, iron, and calcium due to the disruption of the normal gastric anatomy and physiology. Bariatric surgery can lead to altered dissolution and/or absorption of many medications due to reduced surface area for intestinal and gastric absorption, and alterations in drug metabolism via the intestinal metabolic pathways.

10. **D.** Significant reduction in risks of myocardial infarction, cardiovascular deaths, incidence of type 2 diabetes mellitus, hypertension, dyslipidemia, and cancer have also been documented after adult bariatric surgery.

11. **D.** The 2015 Endocrine Society Clinical Practice Guideline for the Pharmacological Management of Obesity recommend against the use of sympathomimetic agents, such as phentermine, in patients with uncontrolled hypertension or a history of CVD.

12. **B.** Adverse medication reactions associated with the use of semaglutide are similar to those reported with liraglutide and include nausea, diarrhea, constipation, vomiting, dyspepsia, and abdominal pain. Semaglutide has also been associated with rare cases of acute pancreatitis, acute gall bladder disease, acute kidney injury, diabetic retinopathy, and small increases in resting heart rate.

13. **C.** Based on data from clinical trials, the approved label states that liraglutide therapy should be discontinued if 4% weight loss is not achieved by week 16 because it is unlikely that a benefit will be seen.

14. **A.** Increases in heart rate occurred in approximately 50% of patients receiving phentermine–topiramate during clinical trials. In patients receiving the highest dose, 19% experienced increases in heart rate that were greater than 20 beats/min. Heart rate should be monitored in all patients, particularly those with preexisting CVD.

15. **C.** Based on the 2015 Endocrine Society Clinical Practice Guideline for the Pharmacological Management of Obesity, antidiabetic agents that promote weight loss are metformin, glucagon-like pepetide-1 analogs, or sodium-glucose-linked transporter-2 inhibitors.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e

Chapter e2: Health Literacy and Medication Use

Oralia V. Bazaldua; Norbert Rosario; Erica Torres

KEY CONCEPTS

KEY CONCEPTS

① Limited health literacy is common and must be considered when providing medication management services.

② Some groups of people are at higher risk for having limited literacy skills, but in general, you cannot tell by looking.

③ Patients with limited health literacy are more likely to misunderstand medication instructions and have difficulty demonstrating the correct dosing regimen.

④ Limited health literacy is associated with increased healthcare costs and worse health outcomes, including increased mortality.

⑤ Despite numerous efforts to improve safe medication practices, current strategies have been inadequate, and this may have a larger impact in patients with limited literacy.

⑥ Most printed materials are written at higher comprehension levels than most adults can read.

⑦ The United States Pharmacopeia has set new standards for prescription medication labeling to minimize patient confusion.

⑧ Several instruments exist to measure health literacy, but some experts advocate "universal precautions" under which all patients are assumed to benefit from plain language and clear communication.

⑨ Obtaining a complete medication history and providing medication counseling are vital components in the medication management of patients with limited health literacy.

BEYOND THE BOOK

BEYOND THE BOOK

Watch the YouTube video, "Health and the City" available online (https://youtu.be/ux6c3wYzRJM), and the TEDx Talk, "Are You Confused About Health Information? You're Not Alone."

Another exercise is useful for translating the material in this chapter to your local area. Working in small groups, make a list of the challenges in health literacy common in the geographic area your educational institution serves. Use resources such as census.gov and cdc.gov to explore the languages spoken in your area, the racial/ethnic background of residents, and cultural practices that can affect patient adherence to medication-related advice and counseling.

INTRODUCTION

Every day, thousands of patients are not taking their medications correctly. Some take too much. Others take too little. Some use a tablespoon instead of a teaspoon. Parents pour an oral antibiotic suspension in their child's ear instead of giving it by mouth because it was prescribed for an ear infection. Others are in the emergency department because they did not know how to use their asthma inhaler. It is not a deliberate revolt against the doctor's orders but rather a likely and an unfortunate result of a hidden risk factor—limited health literacy.

① *Literacy*, at the basic level, is simply the ability to read and write. When these skills are applied to a health context, it is called *health literacy*, but health literacy is more than just reading and writing. The definition of health literacy has evolved from that of the Institute of Medicine in 2004 as some have questioned its meaning and point out the lack of consensus on what it represents.[1] To update and address health literacy in Healthy People 2030, Santana and colleagues provide the following definitions that address both personal and organizational health literacy. Among other key points, they incorporate a public health perspective and acknowledge that organizations have a responsibility to address health literacy as well.[2]

- **Personal health literacy** is the degree to which individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.
- **Organizational health literacy** is the degree to which organizations equitably enable individuals to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.

While some have provided a rigorous definition for medication literacy,[3] *we propose that* ***medication literacy*** *is simply, the degree to which individuals have the ability to make informed decisions that lead to safe and effective medication use.*

Regardless of the definition, a growing body of evidence associates low health literacy with less understanding, worse outcomes, and increased cost.[1] These poor outcomes have led this topic to receive national attention by multiple government agencies including the Institute of Medicine (IOM), the National Institutes of Health (NIH), the Network of National Libraries of Medicine (NNLM), the Agency for Healthcare Research and Quality (AHRQ), and Healthy People 2030. In 2010, a National Action Plan to Improve Health literacy (Table e2-1) was developed by the US Department of Health and Human Services (HHS), and it provides a blueprint for efforts to improve health literacy across all sectors involved in health information and services. Using the first three goals, the US Centers for Disease Control and Prevention (CDC) adapted this blueprint to develop the CDC Action Plan to Improve Health Literacy in 2021.[4] Other countries have also included health literacy as a key priority in their policies and the World Health Organization (WHO) recommends health literacy as an instrument for achieving several key targets.[1] Indeed, health literacy should be a priority worldwide for the medical community, as its consequences are far-reaching and cross-cutting.

TABLE e2-1

Goals of the National Action Plan to Improve Health Literacy

Goal 1	Develop and disseminate health and safety information that is: • accurate • accessible • actionable
Goal 2	Promote changes in the healthcare system that improve: • health information • informed decision-making • communication • access to health services
Goal 3	Incorporate accurate, standards-based, and developmentally appropriate health and science information and curricula in child care and education through the university level
Goal 4	Support and expand local efforts to provide: • adult education • English language instruction • culturally and linguistically appropriate health information services in the community
Goal 5	Build partnerships, develop guidance, and change policies
Goal 6	Increase basic research and the development, implementation, and evaluation of practices and interventions to improve health literacy
Goal 7	Increase the dissemination and use of evidence-based health literacy practices and interventions

Data from Reference 6.

More than one of every three American adults has difficulty understanding and acting on health information.[5] Patients with limited health literacy have less knowledge about how to manage their disease[1]; they misunderstand dosing instructions and warning labels on medication containers,[6,7] are less likely to read or even look at medication guides,[8] have limited ability for medication management because of limited ability to identify or distinguish their medications from one another,[9,10] and are less able to use a metered-dose inhaler (MDI) properly.[11] Limited health literacy skills have also been documented in caregivers of seniors and in parents of children. There is no question that limited health literacy is associated with adverse health outcomes including an increased mortality rate[12] and increased healthcare costs.[1]

Current strategies for safe medication use have not been effective for the general population and are likely less useful for persons with limited health literacy. All health professionals need to acknowledge that limited health literacy is common and may be a barrier to improving health outcomes in their patients. They need to implement strategies for clear communication in order to enhance appropriate medication management. This chapter will review what is known about health literacy and present the evidence available as it relates to medication use.

PREVALENCE

According to the National Assessment of Adult Literacy (NAAL), 36% of Americans have limited health literacy skills, meaning that out of four levels, they function at the lowest two.[5] The NAAL survey was administered randomly to 19,000 adults (greater than or equal to 16 years of age) across the United States, and final results were reported in four skill levels: below basic, basic, intermediate, and proficient. Fourteen percent of Americans had health literacy skills that were considered below basic, 22% were at the basic level, 52% were at intermediate, and only 12% were considered proficient (Fig. e2-1). The *below basic* level is substantially below that which is necessary to function within the healthcare setting. Individuals in the *basic* level have skills to perform simple everyday literacy activities. They can read, understand, and use information in short and “simple” documents. *Intermediate* literacy levels include skills necessary to perform moderately challenging literacy activities. (Note that the NAAL considered interpreting prescription drug labels an intermediate-level task.) Individuals in the *proficient* level would have the least difficulty navigating the healthcare system. This group can analyze, integrate, and synthesize complex information. Approximately 3% of people surveyed were excluded from the analysis due to language barriers or cognitive disabilities. Thus, if you extrapolate and add this 3% to the 36% of people who measured at the two lowest levels and consider the estimated American population of 2020, approximately 130 million Americans have limited health literacy.[5,13]

FIGURE e2-1

Percentages of Americans aged 15 years or older in health literacy levels. (*Data from Reference 5.*)

GROUPS AT HIGH RISK

② It is generally not possible to tell if someone has limited health literacy simply by looking at or talking to them. Many persons with limited health literacy learn to hide it well and many are known to keep this secret to themselves. In one study, two-thirds of persons surveyed (68%) admitted to not telling their spouse about their reading difficulties and more than one-half had not told their children.[14] In a study of internal medicine residents and students, few of them recognized low literacy as a potential factor in patient nonadherence and hospital readmission.[15] It is important to note that health literacy is a context-dependent skill, meaning that people who function well in one environment may still struggle when presented with healthcare tasks. Thus, even people with adequate education levels may find it difficult to navigate the healthcare system due to lack of familiarity with the context. While it is important to remember that people of all ages, nationalities, and income groups are at risk for limited health literacy, there are some groups that are at particularly high risk that should be mentioned (Table e2-2).[5] This information can help assess the potential risk of limited health literacy in the patient population being served.

TABLE e2-2

Groups at High Risk of Limited Health Literacy

Age 65 years or older
Minorities
Spoke another language prior to formal education
Have less than a high school diploma
Live at or below the poverty line
Rate their overall health as poor
Have Medicaid, Medicare, or no insurance

Data from Reference 5.

As the Latino population in the United States continues to increase, this group and those with limited English proficiency (LEP) are at a high risk for limited health literacy and inappropriate medication management as they have lower health literacy scores.[5] Unfortunately, most pharmacies in the United States are not equipped with appropriate translation or interpreter services. In a telephone survey of 764 pharmacies, nearly 57% reported limited or no translation services available.[16] In fact, 45% of pharmacies admit to not being satisfied with their ability to communicate with patients that have LEP. In 2012, the United States Pharmacopeia (USP) set new standards for prescription container labeling and recommends that whenever possible, directions be provided in the patient's preferred language as well as English to minimize the risk of misinterpretation.[17]

Practices that serve Latinos or patients with LEP should be cognizant of their high risk and employ strategies for providing clear communication about appropriate medication management.

Children

What happens when adults with limited literacy become parents? Not surprisingly, a systematic review of the literature concludes that child and parent literacy seem to be associated with important health outcomes. Similar to data found in adults, children with limited literacy had worse health behaviors. These include a decreased ability for the parents and caregivers to safely and effectively use over-the-counter medications. If their parents had limited literacy skills, these children had worse health outcomes such as 50% more emergency department (ED) visits. In children with asthma, limited parental health literacy is associated with a greater incidence of emergency department visits, hospitalizations, missed school days, and greater use of rescue medications.[18] In another study, caregivers with low health literacy were more likely to report the use of a non-standardized dosing instrument.

While interventions in general are lacking, there are more that target improvement in knowledge than outcomes. One intervention using pictograms, brief counseling, and the teach-back method improved the likelihood of parents correctly dosing medicines and adhere to the regimen. Similarly, parents with low health literacy were less likely to make a dosing error with infant acetaminophen after receiving text-plus-pictogram instructions compared to text-only recipients. As in the adult population, effective interventions that improve outcomes and minimize health disparities are needed.

CONSEQUENCES

Table e2-3 provides a comprehensive list of studies to date evaluating health literacy and medication use. In particular, it provides a summary of the studies evaluating the effect of health literacy on medication knowledge and understanding, medication management, and medication adherence. One study evaluated the effect of health literacy on adverse drug events and found no association.[19]

Decreased Knowledge and Understanding

A number of studies have shown that patients with limited health literacy have less knowledge about their disease and how to manage it. For example, among patients with diabetes, 94% of those with adequate health literacy knew the symptoms of hypoglycemia, compared with only 50% of those with inadequate health literacy.[38] Similarly, persons with limited health literacy did not know about factors that could lower blood pressure such as weight loss and exercise. Other studies have also correlated limited health literacy with less knowledge about asthma, reproductive health, human immunodeficiency virus (HIV) infection, discharge instructions, and heart health.[39]

Several studies also confirm the association between limited health literacy and decreased understanding of appropriate medication use.[6–8,24] A study to examine patients' ability to understand instructions on medication labels concluded that lower health literacy was independently associated with misunderstanding of instructions.[6] Patients with inadequate and marginal health literacy had a relative risk of 2.32 and 1.94 of misunderstanding label instructions, respectively.

Warning labels are routinely used with prescription medications, yet a recent study indicated that these labels may not be useful for patients with limited health literacy. In fact, patients with low health literacy have a three times greater likelihood of incorrect interpretation of prescription warning labels and have a potential for misuse of their medications.[7] For example, in the warning label that states, "Do not chew or crush, swallow whole," some patients were interpreting it as "chew pill and crush before swallowing." Another study found an association between limited health literacy and deficits in warfarin-related knowledge.[21]

Lastly, patients with limited health literacy have difficulty understanding medication guides, which are educational materials mandated for some products by the FDA, and most admit to never looking at them.[8]

Decreased Ability for Medication Management

③ Limited health literacy has also been associated with a decreased ability for "medication management"—the ability to self-administer a medication regimen as it has been prescribed.[9] Examples of functional skills necessary for medication management include correct identification of medications, opening the appropriate containers, proper selection of the correct dose, and timing of administration, as well as appropriate use of containers such as MDIs, nasal sprays, and eye drops.

Studies indicate that patients with limited health literacy are unable to name or identify their own medications.[9,10] Persell and colleagues conducted a study to assess the relationship between health literacy and patient recall of their antihypertensive medications.[10] He found that only 40.5% of patients with inadequate health literacy were able to name any of their antihypertensive medications, compared to 68.3% of those with adequate health literacy. In this same study, inadequate health literacy was also associated with a greater number of unreconciled medications (64.0% vs 37.8%). Similarly, in another study, patients with inadequate literacy skills had 10 to 18 times the odds of being unable to identify all of their medications, compared with those with adequate literacy skills.[9]

In a study to determine the relationship of literacy to the MDI technique of asthma patients, researchers concluded that inadequate literacy was strongly correlated with improper MDI use.[11] Compared with patients with adequate health literacy, more patients with inadequate health literacy were unable to demonstrate proper MDI use (88% vs 48%).

Uncertain Effect on Medication Adherence

Results of studies evaluating the relationship between limited health literacy and medication adherence are conflicting. Several studies in patients using antiretroviral medications for the treatment of HIV infection indicate that patients with limited health literacy are less likely to be adherent to their medications.[24–26] Persons with inadequate health literacy were more likely to have lower refill adherence,[27] decreased medication taking,[28] and more likely to have unintentional nonadherence after a hospital discharge.[29] In contrast, several studies concluded that health literacy is not independently associated with adherence,[34–36] another study showed a strong trend,[37] and yet another study actually found an increase in adherence.[33]

A major barrier to consolidating data from adherence studies is that there is no generally accepted “gold standard” for measuring medication adherence, making overall conclusions difficult. Further studies are needed to adequately determine the true relationship between health literacy and medication adherence.

Worse Health Outcomes

The AHRQ has published two reports that summarize the literature available regarding the association between health literacy and outcomes.[40,41] In the first report, they identify most of the studies evaluated as being “fair or good,” and overall, they report that there is an association between lower literacy and adverse health outcomes.[40] In one study evaluating the association of health literacy with diabetes outcomes, the investigators found that patients with limited health literacy have worse control of their diabetes and are more likely to report complications such as retinopathy and cerebrovascular disease.[42] In a recent study, the majority of patients with poorly controlled diabetes (A1c greater than 8%) were more likely to believe that their diabetes was well controlled if they had low health literacy. Thus, they may be less likely to make changes to improve control.[43]

The second AHRQ report reinforces the initial link between limited health literacy and worse health outcomes.[41] Patients with limited health literacy have a higher risk for emergency care use, less use of preventive services, poorer skills in taking medications, and more hospitalizations. Low health literacy was also found to be a significant, independent risk factor for hospital reutilization within 30 days after hospital discharge.[44] This can be costly since accountable care organizations will be reimbursed less for hospital reutilization within 30 days of discharge.

Unfortunately, inadequate health literacy has even been linked to increased mortality in community-dwelling elderly persons.[12] Baker and colleagues studied 3,260 Medicare managed-care enrollees to determine whether low health literacy independently predicted all-cause mortality. Crude mortality for persons with inadequate health literacy levels was more than twice as high as in those with adequate health literacy (39.4% vs 18.9%). Even after adjusting for confounding factors such as demographics, socioeconomic status, and baseline health, participants with inadequate health literacy had a hazard ratio of death of 1.52 compared with participants with adequate health literacy. The authors concluded that inadequate health literacy independently predicts all-cause mortality in community-dwelling elderly persons. A different study of older adults confirmed the increased risk of mortality in those with low health literacy (hazard ratio = 1.40).[45] In a cohort study of patients hospitalized for acute heart failure, low health literacy was associated with a 32% increased risk of death. This increase was found after adjusting for age, gender, race, insurance, highest level of education, hospital length of stay, and comorbid conditions.[46] A recent review of health literacy and outcomes reinforced previous data and noted that patients with heart failure and low health literacy had greater rates of readmission and cardiac mortality.[47]

Increased Healthcare Costs

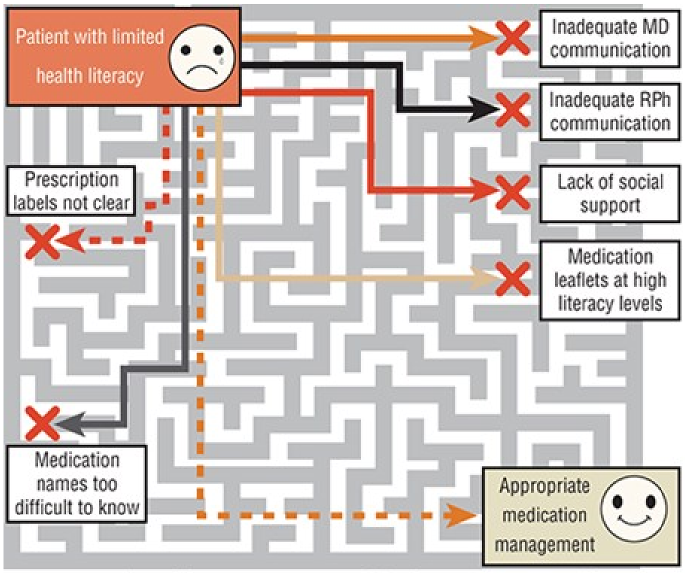
④ A systematic review concludes that the economic implications of limited health literacy are substantial.[48] Patients with limited health literacy tend to seek medical care when they are sicker, leading to higher use of emergent care and longer hospitalizations. Thus, it is no surprise that caring for persons with limited health literacy is associated with higher healthcare costs. At the health system level, limited health literacy may account for a 3% to 5% increase in total costs.[48] The increased cost at the individual patient level may range anywhere from $143 to $7,798. Howard and colleagues found that persons with inadequate health literacy incur higher healthcare costs and use medical services inefficiently, especially emergency department care.[49] Another approximation of the cost of limited health literacy to the American economy ranged from $106 to $238 billion annually, equal to about 7% to 17% of all personal healthcare expenditures.[50] A large-scale study demonstrated higher healthcare costs in the Veterans Health Administration (VHA) patients. Of 92,749 veterans, the mean per patient cost for those with inadequate and marginal health literacy was significantly higher ($31,581) compared with the cost of those with adequate health literacy ($17,033). It is estimated that the healthcare cost of veterans with marginal and inadequate health literacy was $143 million dollars more over a 3-year period.[51] A brief summary outlining the cost of low health literacy estimates an increased cost to hospitals of $12.6 billion per year. This author reinforces the importance of taking time to help patients understand their medications and address obstacles to obtain their best possible outcomes.[52]

SHORTCOMINGS OF CURRENT SAFE MEDICATION PRACTICES

⑤ Despite our most sophisticated efforts to encourage safe medication use, our current strategies have been insufficient and ineffective, especially for patients with limited health literacy. Figure e2-2 depicts the maze of medication information that patients are expected to navigate and several of the barriers that patients with limited health literacy may encounter.

FIGURE e2-2

Medication information maze. Communication barriers and the complexity of current medication information make it difficult for any patient to achieve appropriate medication management, but these barriers are even more significant in a patient with limited literacy skills.



Patient with limited health literacy
Inadequate MD communication
Inadequate RPh communication
Lack of social support
Medication leaflets at high literacy levels
Prescription labels not clear
Medication names too difficult to know
Appropriate medication management

Patient Information Leaflets

⑥ Although the average American adult reads at about the eighth-grade level, numerous studies indicate that most handouts exceed this level.[53] In a survey of 251 primary care adult patients, only 23% reported having ever looked at the accompanying medication guides. Patients with lower literacy were less likely to have looked at the medication guides (16.7% vs 32.9%). Because of this, and the fact that the medication guides were written at the 11th and 12th grade level, the authors concluded that they probably were not useful to patients with limited literacy skills.[8] Raynor and colleagues also found that consumer medication information handouts do not meet people's information needs. People did not value the written information they received about medicines, and providing the leaflets did not increase their knowledge. People tended to want information that was tailored to them with a balance of both benefit and harm. They also wanted information before the drug was prescribed to decide if it was the right medicine for them; this is often not done. Overall, they found a gap between what the patients wanted and what the medicine leaflets provided.[54]

Medication Labels

Poor medication labeling has been cited as a potential cause for medication errors. Indeed, the USP attributes about one-third of all medication errors to confusion with product labeling.[55] Shrank et al. assessed 85 labels on pharmacy-dispensed medications for format, context, and variability. Their evaluation concluded that the most prominent portion of the label included the name of the pharmacy or logo in 84% of all the labels reviewed. In addition, the smallest font sizes were used to display the medication name (an average of 8.9 points) and medication instructions (9.3 points). Color and boldface were used to highlight items most useful to the pharmacist as opposed to highlighting the information that is most useful to the consumer. Warning instructions were highly variable among all labels depending on the pharmacy.[56]

⑦ A group of health literacy experts has pointed out, “inadequate patient understanding of prescription dosing instructions and warnings is prevalent and a significant safety concern.”[57] In a report published by the IOM, experts advocate for standardization of prescription medication labels in efforts to minimize patient confusion and improve patient safety. This report examines what is known about how medication-container labeling affects patient safety and discusses evidence-based approaches to address the identified problems. As precedents for such national standards, the report cites the successfully reformed nutrition facts on food product labels and standardization of over-the-counter labels by the FDA.[57]

Based on the available evidence and expert recommendations, the USP released a new set of standards in 2012 for patient-centered medicine labels.[17] Enforcement will be at the discretion of each state, but it is expected that applying these standards will reduce adverse drug events and medication misuse. The standard provides a universal approach on how prescription labels should be organized in a “patient-centered” manner. For example, the label should include the indication for use and provide explicit instructions in the patient's preferred language. Medical jargon should be avoided. For instance, use *heart* instead of *cardiac* and use numeric instead of alphabetic characters (eg, *2*, not *two*). A list of USP standards is presented in Table e2-4 with examples that incorporate them shown in Fig. e2-3.

TABLE e2-4

USP Prescription Container Label Standards to Promote Patient Understanding

Standards	Description
Organize the prescription label in a patient-centered manner	Place label elements in an order and format that makes it easy for patients to find and understand
Emphasize instructions and other information important to patients	Format the label in a way to stress what is essential to the patient by: • Making prominent the information that patients must have in order to use medications correctly and safely (ie, patient name, drug name and strength, and directions) • Placing dosing instructions in the same order every time (ie, dose > route > frequency) • Making less prominent and placing away from dosing instructions less important information such as pharmacy name, prescriber, fill date, etc.
Simplify language	Use simple, clear, and concise language that avoids unfamiliar words and medical jargon
Give explicit instructions	Use unambiguous dosing instructions by: • Using numbers instead of words (ie, 2 instead of two) • Use explicit time periods such as morning and evening instead of twice a day • Avoid wording such as “take as directed”
Include purpose for use	Unless the patient objects when asked, include on the label in simple terms the indication included on the prescriber's prescription (ie, high blood pressure instead of hypertension)
Limit auxiliary information	Present in simple explicit language only the information essential for patient's understanding and safe medication use
Address limited English proficiency	Provide label directions in the patient's preferred language when possible
Improve readability	Among many other recommendations to make labels easy to read include: • High contrast between font and background • Simple fonts such as Arial or Times New Roman • Normal sentence capitalization (not all capitals or all lowercase) • Adequate white space between lines of text as well as sections of the label • Horizontal text only (no vertical warning labels) • Not abbreviating important information

Data from Reference 30.

FIGURE e2-3

Examples of evidence-based medication labels incorporating recommendations from the ACP and United States Pharmacopeia, Chapter 17.[17,57,58] Notice that the most important parts are in the left section, in larger font, and highlighted. Numbers are used instead of words; directions are explicit and on individual lines. These labels also include the indication for use in the upper right section, and a Universal Medication Schedule (UMS) graphic in the lower left. (*Data from References* 58 and 59.)

In addition to the USP standards, the American College of Physicians (ACP) Foundation also recommends the use of a universal medication schedule (UMS) to convey and simplify dosage and/or use instructions; a visual aid with standard intervals (eg, morning, noon, evening, and night) can simplify dosing and reinforce text instructions (see the bottom of Fig. e2-3).[57,59]

Counseling by Physicians and Pharmacists

Communication failure has been reported to be the underlying cause of about 10% of adverse drug events.[60] Patients with limited health literacy are significantly less likely to ask questions of their providers.[61] About one-half of the prescriptions taken each year are used improperly, and an estimated 96% of patients do not ask questions about their medications.[62]

Unfortunately, provision of verbal counseling by prescribers and pharmacists has been disappointing. Though the exact prevalence of counseling behaviors is uncertain, the Healthy People 2010 Final Review indicated that patients received verbal counseling about 26% of the time from prescribers and only 6% of the time from pharmacists.[63] In addition, when physicians make an effort to communicate when prescribing new medications, they often fail to communicate critical elements of medication use. Tarn et al. found that physicians only communicate about three of the five expected elements of drug information (name of medication, purpose, dose and timing, duration, and adverse effects) when initiating new prescriptions.[64] Furthermore, in 2011, only 64.1% of adults reported that instructions from healthcare providers were easy to understand.[65]

In efforts to improve these numbers and thus medication safety, Healthy People 2030 included several objectives involving the quality of communication between patients and their healthcare providers. Specific goals include increasing the proportion of adults whose healthcare providers check their understanding of instructions from 26.6% to 32.2% and decreasing the proportion who report poor communication with their healthcare providers from 8.9% to 8%.[66]

Medication Names

Each year, the FDA approves dozens of new molecular entities, all of which need brand and generic names. Despite the intricate process of naming a drug and guidelines developed by the United States Adopted Names Council, drug mix-ups still occur in the dispensing process.[67] If these mix-ups occur with health professionals, imagine the confusion it causes to the consumer with limited health literacy. It can be overwhelming and dangerous.

A 2007 study assessed the relationship between health literacy and patient recall of their antihypertensive medications. Overall, regardless of their literacy level, more than 40% of patients were unable to name any of their antihypertensive medications. When considering literacy levels, patients with limited health literacy fared worse in terms of recalling the names of their blood pressure-lowering medications (31.7% vs 59.5%). After adjusting for age and income, this difference was almost threefold (odds ratio 2.9).[10] In another survey of 100 patients, researchers found that participants could provide the names of only 55.8% of their medications.[23]

The United States Adopted Names Council follows a set of guiding principles when naming new medications. The first guiding principle is "A nonproprietary name should be useful primarily to healthcare practitioners, especially physicians, pharmacists, nurses, educators, dentists, and veterinarians."[68] Notice that *consumers* or *patients* are not considered in this guiding principle, even though they are the ones who need to know the name the most. We should resolve to do better.

METHODS FOR IDENTIFYING PATIENTS WITH LIMITED HEALTH LITERACY

Informal Assessments

The shame associated with limited literacy often prevents patients from receiving appropriate medical care, as they tend to hide their reading problem. In addition, healthcare providers often do not consider low health literacy in their patient care.[15,69] As previously mentioned, certain groups are at higher risk for limited health literacy, but even people with adequate literacy levels who are unfamiliar with the healthcare context may have difficulty navigating the healthcare system and often go undetected.

Common Signs

The following are common signs that may suggest a person has limited health literacy skills[14,70]:

1. Reads slowly
2. Has difficulty telling a coherent story
3. Fills out forms incorrectly or incompletely
4. Uses excuses such as, "I forgot my glasses," "I'll read this later," or "I don't have time to read this now. Can I take it home?"
5. Brings along a friend or family member for assistance
6. Fails to show up for appointments or is late for refills
7. Does not ask questions for clarification
8. Has difficulty following instructions
9. Nods in agreement or expresses understanding but does not truly understand information

Medication Review

A medication review may be useful in identifying patients with limited health literacy skills. If the refill history is accessible, one might find that they often forget to refill their medications on time or never pick them up. They may not be able to verbalize a list of their medications despite having a short list. If the medication bottles are available, the patient can be asked to state the name, use, and dosing instructions for each of their medications. Patients with limited health literacy may not be able to respond accurately. They may say, "I take them just like it says on the bottle," or they have to look at the pill color and shape before they can respond.

If patients have a medication reconciliation list from their last visit, they may hand over the list to the health professional and say, "This is everything that I am taking." However, when probing a little further, they likely do not know the contents of that list, and it may not be exactly what they are taking. When asked to read a medication label that says, "Take one tablet by mouth once daily at bedtime," they may recognize the pill and say it reads, "Take one every day," because they have memorized the instructions that may or may not match the container label. When picking up refills, patients with limited health literacy may ask the pharmacist for the old bottles because they depend on their personal markings such as an *X* on the cap.[71]

Formal Measures

⑧ Because of the high prevalence of inadequate health literacy, many experts recommend that health professionals practice "universal precautions" by trying to communicate as clearly as possible with *all* patients and family members.[72] Others suggest that professionals should screen patients' health literacy and then tailor communications accordingly. It is not clear which approach is best.

A number of instruments have been developed to assess health literacy in both English and Spanish. These instruments can identify patients with "low," "marginal," "inadequate," or "below basic" skills, all of which mean that the patient has limited health literacy. An article by Mancuso provides a comprehensive review of health literacy assessment tools.[73]

Two of the most widely used measures of health literacy are the Rapid Estimate of Adult Literacy in Medicine (REALM) and the Test Of Functional Health Literacy in Adults (TOFHLA). These tests are mainly used in research, but they can be used in practice.[73] Additionally, a survey revealed that patients do not mind having their literacy assessed in the clinical setting. More than 98% of patients agreed to a literacy assessment in a routine health visit, including 46% of patients with limited literacy skills.[74]

The REALM is a word-recognition test and estimates health literacy based on patients' ability to pronounce a list of medical terms. The TOFHLA consists of a reading comprehension section to measure prose literacy and a numeracy section. Passages with health information have words that have been deleted, and the patient is to choose the correct word from a list of four options. The Newest Vital Sign (NVS) assesses health literacy by having patients review a nutrition label and answer six questions about the label.[73]

While there are continued calls for comprehensive measures of health literacy, there is just as much interest in developing specialized versions, as well as short versions of instruments for rapid assessment of literacy skills. Helitzer and colleagues have developed a disease-specific web-based tool called TALKDOC which measures women's health literacy of Human Papilloma Virus and cervical cancer.[75] The Parental Health Literacy Activities Test (PHLAT) and its Spanish version have been developed to assess the literacy and numeracy skills, such as preparing infant formula correctly and dosing medication accurately, that parents need to safely care for infants and children.[76,77] In addition to shorter versions of the REALM (shortened-REALM) and TOFHLA,[73] one-item measures have been developed and evaluated for rapid screening of health literacy skills which have subsequently been incorporated into a four-item brief health literacy screening tool called BRIEF.[78] The Recognize and Address Limited Pharmaceutical Literacy Skills (RALPH) interview guide was developed to assist pharmacists in assessing patients' medication literacy, or their ability to understand and apply instructions for safe and effective medication use, during a typical patient counseling session.[79]

As with all tests, each has its limitations. For example, S-TOFHLA does not assess numeracy unlike its parent test, TOFHLA.[73] While the NVS was validated in people of all races with an average age of 41 years, a smaller study of African Americans with a mean age of 73.2 years determined that the NVS took 8 minutes longer to administer and was overall not as applicable in this age group.[80] Griffin et al.[81] and Haun et al.[82] found significant variation in categorizing test-takers between inadequate and marginal health literacy in groups given both the REALM and S-TOFHLA assessments. Further, the BRIEF tool was validated in a predominately white male English-speaking veteran population which may not be generalizable to other populations.[78] While the RALPH interview guide was designed for seamless incorporation into a medication counseling session, its linkage to each patient's unique medication regimen and lack of objective, uniform scoring limits its utility in research.[79]

Table e2-5 provides a list of these commonly used assessment tools.

TABLE e2-5

Methods to Assess Health Literacy

One-Item Measures[78,83]	Length (minutes)	Interpretation/Scoring
"How confident are you filling out medical forms by yourself?" (0, extremely; 1, quite a bit; 2, somewhat; 3, a little bit; 4, not at all) "Qué tan seguro(a) se siente al llenar formas usted solo(a)?" (0, extremadamente; 1, mucho; 2, algo; 3, un poco; 4, para nada)	≤1	Positive answers for low health literacy are "somewhat," "a little bit," or "not at all" Positive answers for Spanish speakers are: "a little bit" or "not at all"

"How often do you have someone help you read hospital material?" (0, none of the time; 1, a little of the time; 2, some of the time; 3, most of the time; 4, all of the time)	≤1	Positive answers are "some of the time," "most of the time," and "all of the time"

Multi-item Measures

Assessment Tool	Description	No. of Items	Length (minutes)	Interpretation/Scoring
National Assessment of Adult Literacy (NAAL)[5]	Main purpose was to measure general literacy but included items specifically to assess health literacy	28	(Not for practice; survey done every 10 years)	Below basic Basic Intermediate Proficient
Shortened rapid estimate of adult literacy in medicine (Shortened-REALM)[73,a]	Word recognition list. Patients read a list of 66 common medical words and are scored on correct pronunciation	66	2-3	0-44 Low 45-60 Marginal 61-66 Adequate
Short test of functional health literacy in adults (S-TOFHLA)[73]	Patients must fill in words that have been deleted systematically from a sample text of common health instructions; words are selected from a list of multiple-choice options. Excludes numeracy testing	36	7	0-16 Inadequate 17-22 Marginal 23-36 Adequate
Short Assessment of Health Literacy for Spanish Adults—50 (SAHLSA-50)[84,a]	Based on REALM and reading a list of common medical words in Spanish (includes two association words; key and distracter)	50	3-6	0-37 Inadequate
Newest Vital Sign (NVS)[73]	Patients review a nutrition label and answer 6 questions about the label	6	3	0-1 indicates >50% likelihood of marginal or inadequate literacy; 2-3 indicates possibility of limited literacy; and 4-6 adequate literacy
Short Assessment of Health Literacy—Spanish and English (SAHL-S&E)[85,a]	Based on REALM and SAHLSA-50 (includes two association words; key and distracter). High correlation between words used in both versions and adequate to compare Spanish and English speakers together	18	2-3	0-14 Inadequate
Brief Health Literacy Screening Tool (BRIEF)[78]	Patients answer four questions and respond on a 5-point Likert scale	4	<2	4-12 Inadequate 13-16 Marginal 17-20 Adequate

Medical Term Recognition Test (METER)[86]	Self-administered medical word recognition test. Contains 40 medical words and 40 nonwords	80	2	0-20 Low 21-34 Marginal 35-40 Functional
Health Literacy Skills Instrument 10-item short form (HLSI-SF)[87]	Based on NAAL with four domains of health literacy skill assessment: reading/writing, numeracy, listening, and information seeking (Internet navigation)	10	5-10	<70% Below basic literacy 70%-81% Basic literacy ≥82% Proficient literacy
Recognizing and Addressing Limited PHarmaceutical literacy (RALPH)[79]	Interview guide for use by pharmacists in patient counseling, with three health literacy domains: functional, communicative, and critical	10	Variable, incorporated into prescription counseling	No objective scoring An inability to discuss medication information or search for medication information indicative of limited pharmaceutical literacy skills

[a] Except for the REALM, a Spanish version is available for all methods. SAHLSA-50 is available only in Spanish.

STRATEGIES FOR CLEAR COMMUNICATION ON MEDICATION MANAGEMENT

Increase Health Literacy Awareness

The first step toward improving communication on medication management in individuals with limited health literacy is to recognize that limited health literacy is common. A survey revealed that pharmacists in only 7% of community pharmacies attempt to identify literacy-related needs among the individuals they serve. Most pharmacists seemed to be surprised and unaware that some of their customers may have difficulty reading.[69] In fact, only 12% of American adults have proficient health literacy skills.[72]

Therefore, it is likely that most health professionals, including pharmacists, will be serving individuals with limited health literacy skills. As such, professional schools should incorporate health literacy into their curricula and areas of competence. Much work remains to be done in this area, but efforts are under way. This chapter itself is a tribute to these efforts.

Some disciplines are promoting health literacy awareness by incorporating the need to address this cross-cutting topic in their accreditation standards.[88] Curricular modules have been developed to introduce pharmacy students to the implications of limited health literacy on medication management and provide them with the tools to address medication adherence barriers. Topics covered include health literacy assessment, critique of patient education materials and medication labels, and communication strategies to promote patient understanding.[89] In an introductory program, third-year pharmacy students determined the impact of using health literacy communication tools in a group of independent-living senior residents. They found that using these health literacy tools increases patient understanding, empowerment, and commitment to medication adherence.[90] Medical schools and residency programs have also explored different ways to incorporate this topic in their training. A 2-hour workshop was developed for physician residents to improve assessment of adherence and their medication counseling skills. One month after this intervention, physicians reported a significant improvement in these areas.[91]

Obtain a Complete Medication History

⑨ Perhaps one of the most essential components necessary to improve medication management in patients is obtaining a thorough and complete medication history. This is important for all patients regardless of their health literacy level. However, because patients with limited health literacy have difficulty naming their medications and are more likely to mismanage their medications, taking a complete, baseline history of what they are taking is especially valuable.

Medication histories are equally important in all clinical settings, including hospitals, communities, home health, long-term institutions, and ambulatory centers. The hospital accreditation body, the Joint Commission, has recognized medication reconciliation (comparing a medication list to what a patient should be receiving) as a crucial step in promoting medication safety and minimizing medication errors. A systematic review suggested that electronic medication reconciliation may contribute to a reduced rate of medication errors and discrepancies at hospital discharge, but study heterogeneity limited definitive conclusions.[92] Further research is necessary to identify medication reconciliation best practices associated with improved patient outcomes.

Table e2-6 provides a list of recommended strategies and questions for obtaining a complete and accurate medication history.[93–95] A video example of how this can be done in a manner sensitive to health literacy is also available at https://youtu.be/It8KfitBeeE.

TABLE e2-6

Helpful Strategies and Questions for Obtaining a Complete Medication History

Preparation

- Before speaking to the patient, if available, obtain a list of their most current medications from their medical records or electronic health system
- This will help elicit information that the patient may have forgotten
- A quick review may also reveal patterns about their refill history

Determine person responsible for medicine regimen

- Do you take your medications on your own or does someone else like a family member or friend help you take them?
- If patient has a caregiver helping with the medication regimen, include them in the interview

General questions

- Do you have your medication containers with you?
- If yes, the patient may use them to proceed and answer the following questions
- If not, ask if they have a list of the medications they take and proceed
- What are your medication allergies?
- How many different doctors write prescriptions for you?
- Which pharmacies do you use to fill your prescriptions? What is their contact information (phone number and address)?
- How do you pay for your medicines? What is the name of your insurance plan?
- What language do you prefer to have on your medicine containers?

Determine complete list of medicines

For each medicine that you take, please tell me the (1) name and dose, (2) the reason you take it (indication), and (3) exactly how you take it. … How many times a day?

Do you take any medicines that you buy over-the-counter without a prescription such as Tylenol or Advil?

Do you take any herbal products, home remedies, vitamins, or other dietary supplements?

Do you take any medicines that you bring from another country such as Canada or Mexico?

Do you take any medicines that are bought over the Internet?

Do you get medicines from other places such as a dialysis unit or another clinic (eg, vitamin B_{12} shots)?

Do you use medicines that are not taken by mouth? For example, patches, inhalers, suppositories, creams, drops, liquids, injectables, nasal sprays?

Do you have medicines that you take only once a week or once a month?

Assess adherence

How do you remember to take your medicines on a regular basis so that you do not forget a dose (eg, pill box, leave pill bottle by toothbrush, set alarm, line up pill bottles)?

How many doses of your medicines have you missed in the last week?

On a scale of 0-10, how well do you remember to take your medicines every day or as prescribed? 0 means you forget to take them all the time, and 10 means you never miss a dose.

When did you take the last dose of each medicine?

If medication containers are available, look at the last refill date and determine if the patient is currently on his or her refills. Look at the date it was filled, how many doses were dispensed, and how many are left now as a rough indicator of adherence.

Data from References 93–95.

Conducting Pharmacy Health Literacy Assessments

A pharmacy health literacy assessment measures how well the pharmacy is serving patients with limited health literacy skills.[96] It is an important first step to improve the quality of medication management for individuals with limited health literacy. The assessment tool developed with funding from AHRQ is comprehensive and is made up of three complementary parts: (1) an "assessment tour" completed by objective auditors (here, barriers for clear communication are noted as well as the physical environment of the pharmacy and staff interaction with patients), (2) a survey completed by staff (this helps determine how "friendly" the pharmacy environment is toward individuals with limited health literacy), (3) focus groups with pharmacy patients (the intent is to collect detailed feedback from patients about their experience with pharmacy services), and (4) using assessment results—after all the data are collected and summarized, a tangible action plan should be developed for improved services to help individuals with limited health literacy.

CREATE EASY-TO-READ MATERIALS

As previously mentioned, efforts should be made to make health information materials easily accessible and understandable, this includes electronic health information.[97–101] eHealth literacy needs tend to be overlooked and not considered when developing eHealth programs.[97] Consider that your audience's reading age is likely lower than you might expect. The average American reads at the 7th to 8th grade level,[98] but unfortunately, most health information is written at a higher grade level.[8] Thus, most sources and studies suggest readability of health information not exceed a 6th-grade reading level.[97–101]

It is important to keep in mind readability and some general principles that are known to make handouts easy to read. They may be helpful either in creating material or as a checklist for determining the appropriateness of a handout. Some of the principles are similar to ones used in verbal communication such as using plain language, focusing on one to three key messages, and incorporating suitable illustrations. The "Plain Writing Act of 2010" Public Law 111-274 requires enhancement of citizen access to information and services; public materials must be written clearly so the public can understand and use the information. This plain-language initiative provides several useful tips on creating written handouts that are easy to read.[102]

An innovative mixed-model approach was used to develop patient package inserts (PPIs). Comprehension scores were 90% in participants with limited health literacy.[103] The three phases included: 1) content development; (2) focus group testing; and (3) comprehension testing. Additionally, a study of hypertension knowledge demonstrated that personalizing health information to learning style preferences and literacy level improves patient understanding.[104] Thus, a number of evidence-based methods and recommendations can contribute to optimal delivery of health information.

Use Interactive Multimedia and Assess the Need for Digital Literacy

Many interventions have shown that interactive multimedia formats (eg, videos, animated characters) are effective in patient educational materials to improve health outcomes in adolescents, older adults, and people with low socio-economic status.[97,105] Positive health literacy effects have resulted from education about websites and online apps, including knowledge of health conditions, use of technology, search skills, use of health information, and confidence in finding and using eHealth resources.

All these improvements contribute to achieving an objective of Healthy People 2030: increasing the health literacy of the population. However, when implementing technical tools, it is important to evaluate and assess the need for digital literacy to ensure patient understanding. Often, while many adults own technical devices, they do not uniformly have the skills or capabilities to properly obtain the necessary online health information.[106] Using interactive multimedia and assessing the need for digital literacy has become even more important with the increased use of telemedicine.[106]

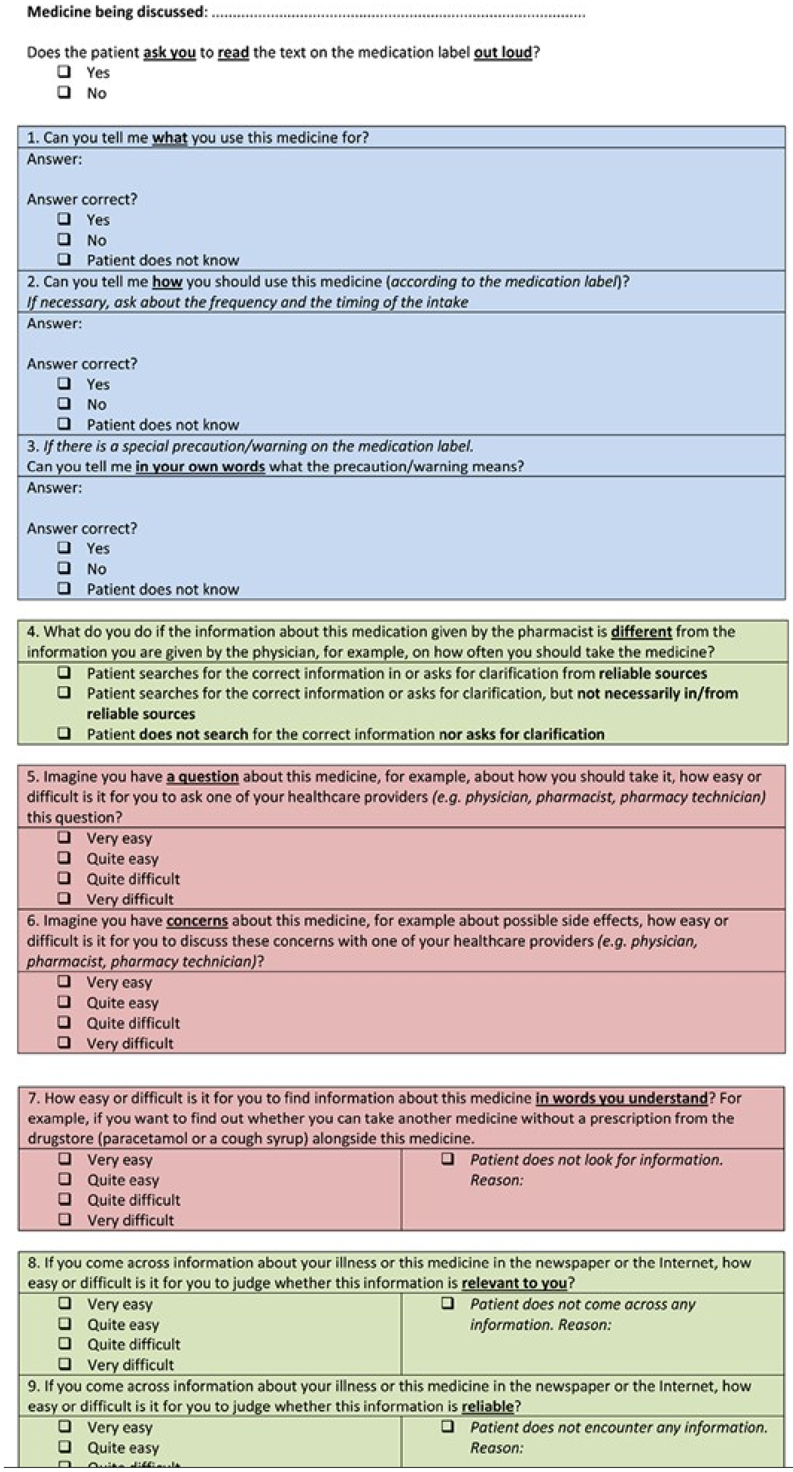
Recognize Limited Pharmaceutical Literacy

It is well known that people with limited health literacy are at higher risk for medication-related adverse outcomes. However, identifying this high-risk population is difficult with the limited tools available to help identify these patients.

Research generally uses multiple tools or measure to assess health literacy and readability of online health information (eg, eHEALS, S-TOFHLA, and REALM). The RALPH interview guide helps shine light on medication/pharmaceutical literacy (see Fig. e2-4).[79] As previously mentioned, the RALPH tool does not provide an objective score but rather an "indication" of whether a patient may be experiencing difficulties with their medications. It supports pharmacists seeking to provide tailored care, improve the comprehension of medication information, and ultimately use of these agents; the tool is also useful in identifying patients who could benefit from teach-back educational sessions.

FIGURE e2-4

RALPH Interview Guide. (*Reprinted from Vervloet M, van Dijk L, Rademakers JJ, et al. Recognizing and Addressing Limited Pharmaceutical Literacy: Development of the RALPH interview guide. Res Social Adm Pharm. 2018;14:805–811.*)



Medicine being discussed: ....

Does the patient **ask you** to **read** the text on the medication label **out loud**?
☐ Yes
☐ No

1. Can you tell me **what** you use this medicine for?
Answer:

Answer correct?
☐ Yes
☐ No
☐ Patient does not know

2. Can you tell me **how** you should use this medicine (*according to the medication label*)?
If necessary, ask about the frequency and the timing of the intake
Answer:

Answer correct?
☐ Yes
☐ No
☐ Patient does not know

3. *If there is a special precaution/warning on the medication label.*
Can you tell me **in your own words** what the precaution/warning means?
Answer:

Answer correct?
☐ Yes
☐ No
☐ Patient does not know

4. What do you do if the information about this medication given by the pharmacist is **different** from the information you are given by the physician, for example, on how often you should take the medicine?
☐ Patient searches for the correct information in or asks for clarification from **reliable sources**
☐ Patient searches for the correct information or asks for clarification, but **not necessarily in/from reliable sources**
☐ Patient **does not search** for the correct information **nor asks for clarification**

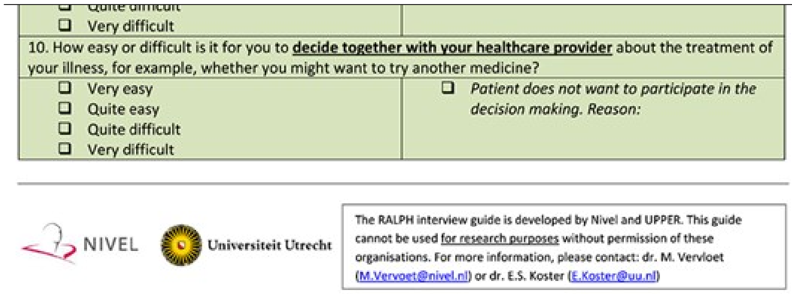
5. Imagine you have **a question** about this medicine, for example, about how you should take it, how easy or difficult is it for you to ask one of your healthcare providers *(e.g. physician, pharmacist, pharmacy technician)* this question?
☐ Very easy
☐ Quite easy
☐ Quite difficult
☐ Very difficult

6. Imagine you have **concerns** about this medicine, for example about possible side effects, how easy or difficult is it for you to discuss these concerns with one of your healthcare providers *(e.g. physician, pharmacist, pharmacy technician)*?
☐ Very easy
☐ Quite easy
☐ Quite difficult
☐ Very difficult

7. How easy or difficult is it for you to find information about this medicine **in words you understand**? For example, if you want to find out whether you can take another medicine without a prescription from the drugstore (paracetamol or a cough syrup) alongside this medicine.
☐ Very easy
☐ Quite easy
☐ Quite difficult
☐ Very difficult
☐ *Patient does not look for information. Reason:*

8. If you come across information about your illness or this medicine in the newspaper or the Internet, how easy or difficult is it for you to judge whether this information is **relevant to you**?
☐ Very easy
☐ Quite easy
☐ Quite difficult
☐ Very difficult
☐ *Patient does not come across any information. Reason:*

9. If you come across information about your illness or this medicine in the newspaper or the Internet, how easy or difficult is it for you to judge whether this information is **reliable**?
☐ Very easy
☐ Quite easy
☐ *Patient does not encounter any information. Reason:*



☐ Quite difficult ☐ Very difficult	
10. How easy or difficult is it for you to **decide together with your healthcare provider** about the treatment of your illness, for example, whether you might want to try another medicine?	
☐ Very easy ☐ Quite easy ☐ Quite difficult ☐ Very difficult	☐ *Patient does not want to participate in the decision making. Reason:*

USE TIPS FOR TELEMEDICINE COMMUNICATION

As a result of the need to adapt care during the coronavirus pandemic, healthcare systems and professionals across the globe increased their use of telemedicine as a means of physical distancing. While this has increased accessibility to many by delivering care via telephone and video in place of in-person visits, many patients struggle with the use of technology (eg, slow internet connections and lack of access, ehealth portals, messaging services, email, downloading and viewing attachments, uploading information and pictures).[101,106] Hence, using plain language and clear communication to decrease barriers for patient understanding is considered a best practice in healthcare (see Table e2-7).

TABLE e2-7

Clear Communication Tips for Telemedicine Encounters

Preparing for encounters
• When making appointments, confirm the patient's phone number and a back-up number if possible • Ask patients to create a written list of concerns in advance • Use easy-to-read informed consent forms, if needed, for virtual visits (https://www.ahrq.gov/health-literacy/informed-consent-telemedicine.html) • Ask patients to gather data, such as vital signs or blood sugar readings, in advance • Ask patients to have prescription medication containers available for reference if needed • Make a backup plan in case the conversation gets cut off • Make sure mobile phones and laptop or tablet computers are charged and have adequate prepaid minutes available when needed • Have pen and paper ready to write a message in case the patient cannot hear you
Privacy
• Both parties should find a quiet and private space to talk, if possible • Position yourself to avoid other people being visible in the background • Turn up volume on devices to a comfortable level • Identify yourself by name, role, and institution • Identify patients with two identifiers such as name and date of birth • Find out who, besides the patient, may be listening in, what their relationship is to the patient, and whether you have permission to discuss personal information • Tell patients if other healthcare personnel may be listening to your conversation • Use a headset to support privacy if needed • Develop and follow a policy for protecting privacy when leaving voice messages for patients
Hearing
• Check that patients are hearing you adequately

- Offer video sign language interpretation or captioning services to people who are hearing impaired

Clear communication

- Use health literacy universal precautions for all encounters
- Use professional medical interpreters when needed
- Establish the agenda at the outset
- Use plain language; avoid unnecessary or undefined medical jargon
- Avoid information overload; focus on 1 to 3 key messages
- Repeat/summarize key information and recommendations
- Use multiple teaching channels when possible, including visual aids and written summaries
- Elicit information using open-ended questions, such as “What questions do you have?”
- Use the teach-back method to confirm clear communication and patient comprehension

Memory aids

- Encourage patients and caregivers to have a pen and paper available for taking notes
- If appropriate, encourage patients to have another person with them to provide a second set of ears
- Arrange for patients to receive a written summary of the encounter

Data from Refernce 101.

Improve Medication Counseling Skills

Perhaps a key point to remember about health and medication literacy is the vital importance of proper medication counseling. The National Conference of Pharmaceutical Organizations (NCPO) agreed that appropriate counseling on the use of medications should be a key goal of healthcare reform in a 2009 policy statement, “From Reform to Revolution: Maximizing the Power of Proper Medication Use in Patient Care.”

In a study of hospital discharge instructions, several interventions were used to educate patients before discharge. The usefulness of each intervention was evaluated with a follow-up telephone call to 125 patients. The three interventions that patients found most useful were (1) speaking with a pharmacist about their medications before discharge, (2) receiving an illustrated medication list, and (3) a follow-up telephone call after discharge. Patients with limited health literacy indicated the greatest benefit.[107]

The following 10 points provide suggestions for pharmacists and other health professionals on how to improve their medication-counseling skills:

1. *Take the time to counsel:* Taking the time to provide verbal counseling about medications is especially crucial in patients with limited health literacy.

2. *Create a relaxed and nonthreatening environment:* Many patients with low health literacy are embarrassed about the difficulty they have understanding health-related information. While they may not take the initiative to disclose this information, they are amenable to discussing health literacy and learning in the right environment. Thus, a first step toward effective medication counseling is to create a friendly and relaxed environment for the patient.[71] Take the time to listen and give the patient enough time to feel comfortable. Try to understand the patient's perspective.

3. *Use plain language:*[108] Speak clearly using plain and common words. Pay attention to the patient's own terms and use them in the medication conversation.[101,108] Table e2-8 has examples of alternative lay terms to common medical terms. Avoid vague terms. For instance, oral and written instructions should be to “take medication 1 hour before breakfast,” not “take medication on an empty stomach.” Tell patients what you want them to do. Use instructions such as, “Stop taking this medicine if you get pregnant,” instead of “this medicine should not be taken during

pregnancy." Another example is, "Do not drink alcohol with this medicine," which is preferred over, "Alcohol should not be mixed with this medicine." In addition, use identifiers such as the time of day. For example, say, "Take 1 tablet in the morning and 1 at bedtime," rather than "take twice daily."

4. *Show the patient each medication while counseling:* Open the medication containers so that the patient can see the colors and shapes of the tablets or capsules.[109] This will help them recall your instructions. For liquids, show patients or caregivers the correct dose with a marking on an oral syringe. These syringes are the most accurate dosing method for liquids.[110]

5. *Focus on one to three key points and repeat them frequently:* Limit the number of messages and tell patients only what they *need* to know. Skip details that are "nice" to know.[108] Reinforce these same key messages by repeating them.

6. *Have patients repeat instructions:* An evidence-based strategy of verifying patient understanding is to use the "teach-back" method.[111] Patients are asked to repeat the instructions or information they were given to ensure that the key concept has been understood and remembered. If the concept is not repeated correctly by the patient, the health professional clarifies and tailors the explanation and reassesses patient recall. This cycle of explaining, assessing, and clarifying is repeated until the concept is understood. This technique is termed "the interactive communication loop in clinician–patient education" by Schillinger and colleagues.[111] They found that when physicians applied this interactive communication strategy for their patients with diabetes, glycemic control improved. Findings of a study assessing patient understanding of prescription labels suggested that professionals should go further by asking patients to "demonstrate" or "show" how they will use medications. Davis and colleagues found that even though some patients could verbalize the correct instructions on the label (eg, take 2 tablets twice daily), they could not "demonstrate" the correct dose.[6] Of note, this group included persons with adequate health literacy levels.

7. *Encourage patients to ask questions:* Never ask, "Do you have any questions?" Instead, ask, "What questions do you have?" Create an environment in which patients feel comfortable asking questions. The professional might say, "Sometimes I give people a lot of information about their medicines and it can be confusing … so I would like to ask you, what questions do you have?"

8. *Use pictures or illustrated medication schedules:* Research indicates that pictures help patients understand how to take their medicines,[112] and these may be particularly useful in patients with limited health literacy skills. A review of the literature found that pictorial aids improve recall, comprehension, and adherence.[113] Researchers have developed prototypes illustrated medication schedules (see Fig. e2-5),[114] as well as a guide on how to create simple versions using word-processing software.[115] These daily schedules provide the patient with a picture of the actual medicine, the name of the medicine, the indication, and specific dosing instructions. Assessment of such tools reveals that more than 80% of patients thought they were useful and easy to understand.[114] Other work confirms that these illustrated daily medication schedules improve medication self-efficacy and adherence among at-risk, community-dwelling older adults.[116]

9. *Supplement the interaction with patient-friendly educational material:* Written medication information can be helpful to supplement and reinforce specific counseling points if it is easy to read. Nonwritten material may also be useful in communicating medication information to patients. Alternative forms to written information include pictures/pictograms, videos, audiotapes, modules on disks, and interactive internet sites. Studies indicate that these modalities are increasingly effective.[97,105] However, some of these new media focus solely on medication information; research on their effectiveness is limited. Table e2-9 provides some helpful resources for pharmacists, other health professionals, and patients.

10. *Review patients' complete regimens and consolidate all medicines into their daily schedule:* In addition to providing information about each individual medication to the patient, it is important to consider the use of agent in the context of the full medication regimen. This is especially necessary when a regimen includes multiple medications, each with specific requirements such as taking on an empty stomach or taking at bedtime. Patients may be easily confused with multiple requirements and either make their regimen more complicated than necessary or compromise their care by not taking their medications appropriately.

FIGURE e2-5

Example of a personalized illustrated daily medication schedule. Such visual tools can help patients keep better track of all the medicines they take on a regular basis. (*For information on how to create such tools, visit:* http://www.ahrq.gov/patients-consumers/diagnosis-treatment/treatments/pillcard/index.html#Acknowledgment.)

Pill Names	Used for?	Instructions	Morning	Afternoon	Evening	Night
Esomeprazole 20 mg	Heartburn	Take 1 pill 1 time a day	1 pill			
Spironolactone 25 mg	Heart	Take 1 pill 1 time a day	1 pill			
Lisinopril 20 mg	Blood Pressure	Take 1 pill 1 time a day	1 pill			
Fluoxetine 20 mg	Depression	Take 1 pill 1 time a day the first 2 weeks. After that, take 2 pills 1 time a day.				
Furosemide 40 mg	Reduce Water	Take 2 pills 2 times a day	2 pills		2 pills

TECHNOLOGY

Technology is now more pervasive and easier to access in the United States than ever. Cellular phones, tablet and other types of computers, and electronic and digital devices such as “smart” thermostats, watches, and medical sensors have become smaller, faster, and cheaper. Their use and adoption have also increased. The percentage of US homes with a computer has risen from 8.2% in 1984 to 92% in 2018. Likewise, Internet use in American homes has increased from 18% in 1997 to 85% in 2018.[117]

Despite these advances, stark disparities remain in technology use and Internet access among Americans based on variations in incomes, education levels, age groups, geography, and ethnicities (Table e2-10).

TABLE e2-10

Computer and Internet Use for Households: 2018

Household Characteristics	% Households with Computers	% Households with Internet Access
Age of householder	97.8	90.9
15-34 years	97.6	91.9
35-44 years	94.3	88.0
45-64 years	80.1	73.2
65 years and older		
Race and Hispanic origin of householder	92.2	86.8
White alone, non-Hispanic	87.8	77.9
Black alone, non-Hispanic	96.5	92.4
Asian alone, non-Hispanic	92.0	82.4
Hispanic (of any race)		
Limited English-speaking household	92.2	86.0
No	82.6	69.9
Yes		
Household income	76.9	64.7
<$25,000	89.7	81.1
$25,000-$49,999	96.3	91.1
$50,000-$99,999	98.5	95.6
$100,000-$149,000	99.0	97.1
$150,000 and more		
Educational attainment of householder	74.9	63.1
Less than high school graduate	85.6	76.6
High school graduate (includes equivalency)	94.6	88.4
Some college or associate's degree	97.8	94.6
Bachelor's degree or higher		

Adapted from File T, Ryan C. Computer and Internet Use in the United States: 2013. American Community Survey Reports, ACS-28. Washington, DC: U.S. Census Bureau; 2014. Available at: http://www.census.gov/library/publications/2014/acs/acs-28.html.

A 2018 US Census Bureau report showed that the majority of households with a computer were English speaking, younger, had a higher income, more education and lived anywhere in the United States. A similar pattern can be seen with regards to Internet access. Only 73.2% of the older population had Internet access. Households that were black or Hispanic (77.9%, 82.4%) tended to have less Internet access compared with whites and Asians (86.8%, 92.4%). Households with Internet access also tended to be English speakers, have a higher income, and more education.[117]

A Pew Research Center survey in 2015 showed that 92% of Americans have a mobile phone (68% smartphones, 34% traditional cell phones). An important finding was 7% that was classified as “smartphone-dependent” users, meaning that they have a smartphone but do not have Internet at home other than their mobile data plan nor do they have other device options for accessing the internet such as a computer or laptop. These users tended to be low-income, black, or Hispanic.[118]

In terms of how smartphones were used, the survey showed that 97% of respondents use their smartphone for text messaging, 92% for calls, 89% for Internet, and 88% for e-mail. Young users (aged 18-29 years) also use their smartphones heavily for social networking services (91%) compared with other age groups. Figure e2-6 shows that 62% of respondents have used their smartphone to look up information about a health condition.[118]

Technology and Health Literacy

Digital health is changing the landscape of healthcare and how involved individuals can participate more in their own care. Unfortunately, access to electronic resources and connectivity may incidentally leave behind populations with the greatest vulnerability. Use of technology by people with low health literacy differs significantly from those with adequate health literacy. Patients can have difficulty discerning what online information is credible and with how to use information in positively affecting their own or another's health. Individuals with adequate health literacy are more likely to contact their healthcare provider through messaging services compared with those with low or marginal health literacy.[119] Additionally, those with low health literacy were more likely to use social networking sites and mobile apps than search engines to obtain health information, and preferred text-limited communication channels (eg, text messaging and radio) to receive this information.[120]

Thus, low health literacy is associated with a digital divide despite increased ownership of smart devices, use of text messaging, and social media. Improvements in care could result from a focus on people's lack of a skill set for performing online tasks, disparities in access, and guiding users to find online and digital health information.

One study showed that in the United States, approximately 77% of the adult population owns a smart device and 15% a wearable device. Approximately 58% of respondents to a large survey reported downloading a mobile health application for improving their health.[100] In a study of digital literacy of hospitalized patients undergoing transitions of care, use of smart devices was lower in those with less health literacy (67.1% vs 78.3% among those with adequate health literacy); Internet access followed this pattern (75.7% vs 90.9%, respectively). Significantly more participants with low health literacy needed assistance in performing online tasks (70.4%) versus those with adequate health literacy (44.6%).[106]

Unfortunately, when it comes to Internet use for accessing patient portals and other online services, patients with low health literacy were 70% less likely to sign on or use the site.[121] Among the 59% of US older adults who use the Internet, an even smaller percentage of those with low health literacy (9.7%) used it for health information purposes compared with those with adequate health literacy (31.9%).[122] As more technology is incorporated into healthcare systems, populations with the greatest vulnerability will need close attention to minimize the already great health disparities.

Technology and Medication Adherence

Table e2-3 shows that the current evidence for the association between health literacy and medication adherence is inconclusive. However, available data indicate that medication adherence is challenging to many people Nationwide, an estimated 75% of Americans have trouble taking their medicine as directed; approximately 125,000 annual deaths result from nonadherence to medications. Indeed, poor adherence is a major public health challenge, and it is logical that people with low health literacy likely have even a bigger challenge.

Current technology trends have helped to address primary nonadherence (not filling or picking up a prescription) by increasing the use of electronic health records (EHRs) to electronically transmit prescriptions or “e-Prescribe” medications directly to the pharmacy. This eliminates the need for patients to carry a paper prescription to the pharmacy. This solution has also allowed for prescription insurance formularies to be available to the prescriber at the point of entry and to reduce patient costs and waiting time by selecting drugs that are less expensive or do not require prior authorizations, both of which are barriers to obtaining medication.

Prescription insurance plans and pharmacies have also begun to share patient claims information, refill history data, and missed refill alerts with connected providers to help reduce duplication, coordinate care, reconcile medications among multiple prescribers, and increase patient safety.

While primary nonadherence and discontinuation of medications are being addressed on a national level, inconsistent use of medication by the individual patient has been a bigger challenge. To improve medication adherence, different technologies are emerging. Table e2-11 provides examples of technologies that can increase medication adherence.

TABLE e2-11

Examples of Electronic Technologies to Improve Medication Adherence

	Examples	Comments
Electronic Reminders	• Alarm clock • Email reminder • Mobile phone calendar • Text messaging • Reminder alerts when doses are due	• Inexpensive • Easily accessible • Sound alerts
Smart Pills **Smart Bottles** **Smart Caps**	• Proteus Discover system • AdhereTech • GlowCap • SMARxT Med Reminder • e-pill Multi-Alarm TimeCap	• Costly • May require Internet/cellular connectivity • Sound and light alerts • Notification and tracking systems • Caution with cap switching
Electronic Medication Dispensers	• MedicaSafe • Philips Medication Dispensing Service • Med-E-Lert Automatic Pill Dispenser	• Moderately expensive • Controlled access capability • Notification and tracking systems • Need to replenish monthly
Mobile Technology[125]	• Smartphone apps (Top 4) ○ Mango Health ○ MyMeds Medication Management ○ MediSafe Meds and Pills Reminder ○ Dosecast Medication Reminder	• Free or inexpensive • Easy to difficult usability • Pictures and visual reminders • May require Internet connection • Gamification and rewards • May be limited by operating system
Directly Observed Therapy[126]	• eDOT	• Use of mobile devices or webcam-enabled computers • Live virtual meetings with clinician at a specific day and time to watch the patient take his or her medication/use inhaler in real time • Could provide immediate instruction or correction to the patient for medication taking or proper device use • Requires Internet connection • May be limited by user/patient or operating system

Two literature reviews provide evidence that text messaging improves medication adherence rates, at least in the first 6 months, but conclude that larger and longer studies need to be conducted.[123,124] Electronic medication dispensing devices, such as MedicaSafe, are available to not only remind patients to take their medication but also allow prescribers to monitor progress. This is important for medications that are costly, such as oral hepatitis C treatments, and when adherence is extremely important, such as with tuberculosis treatment or posttransplant immunosuppression.

Lastly, as mobile technology has become widely available, so have applications (apps) that can be used on smartphone devices. Use of apps for improving medication adherence hasyielded mixed results, but trends indicate overall improvement in self-care behavior and attitudes.[127] One randomized controlled study showed that a Spanish app improved medication adherence in older adults, including some with no experience using this technology.[128] In 2021, Treichler et al. ranked apps based on ratings, availability, and features (Table e2-12).[129] Many other apps are available that connect patients directly to their pharmacy and are designed to provide refill reminders as well as easily request refills.

TABLE e2-12

Top 10 Medication Reminder Apps for 2022

Application Name	Uniqueness	Additional Functions
1. Medisafe	Best overall	Helps caregivers manage prescriptions for loved ones
2. MangoHealth	Best for Android users	Provides rewards for incentives
3. RoundHealth	Best for iOS users	Easy to use and set notifications
4. DoseCast	Best paid app	Can sync reminders across multiple devices
5. MyTherapy	Best for non-English speakers	Available in 30 languages
6. LadyPillReminder	Best for women's health	Birth control reminder
7. CareZone	Best for healthcare management	Keeps track of physician appointments
8. Care4Today	Best for activity tracking	Measures vital statistics
9. MedPlan	Best for health education	Educational tools
10. Groove Health	Best artificial intelligencetool	Can answer questions about medications

Although more studies are needed to evaluate the effect of technology-based adherence interventions, current trials suggest combinations of in-person communication with automated reminders or triggers are more effective.[130]

CONCLUSION

Limited health literacy is a prevalent and often overlooked problem. It continues to be a priority area for the federal government in the United States, numerous national and international organizations, and researchers seeking to improve patients' understanding of health and in turn improve health outcomes.

As technology improves and access increases, improved eHealth interventions that meet the users' needs should be developed. Health literacy leads to improved medication adherence. Health professionals need to consider that many of their patients have limited literacy skills and may also have limited Internet connectivity and/or knowledge and skills needed for using online applications and technology. Health literacy, eHealth literacy, and digital health are important factors to consider in improving appropriate medication use.

SELF-ASSESSMENT QUESTIONS

1. Which of the following factors is associated with the Healthy People 2030 goal for health literacy?

   A. Medication literacy

   B. Personal health literacy

   C. Organizational health literacy

   D. All the above

   E. Only B and C

2. Which of the following are the most widely used measures of health literacy?

   A. TOFHLA and REALM

   B. NVS and S-TOFHLA

   C. PHLAT and shortened-REALM

   D. RALPH

3. Materials should be written at what reading level for most patients to comprehend:

   A. Eighth grade

B. Twelfth grade

C. Seventh grade

D. Sixth grade and below

4. Which of the following is the standard of care or “gold standard” to measure medication adherence?

A. There is no “gold standard”

B. Pharmacy refill history

C. Morisky scale

D. REALM

5. Which of the following are the most vital components in the medication management of patients with limited health literacy?

A. Medication reconciliation

B. Completing a medication history and counseling

C. Medication counseling

D. Provider education on the importance of medication counseling

6. What is a useful strategy to identify patients with limited health literacy?

A. Health literacy questionnaire

B. Pharmacy refill history

C. Medication list

D. Medication review

7. Which of the following groups are at high risk of limited health literacy?

A. Patients with commercial health insurance

B. Age 50 years or older

C. Income at or below the poverty line

D. Patients who rate their overall health as fair

8. Which of the following has been consistently shown as a consequence of limited health literacy in the literature?

A. Decreased ability to name and identify medications

B. Decreased medication adherence

C. Increased understanding of how to take medications

D. No effect on proper use of metered-dose inhalers

9. Which of the following is recommended to improve patient understanding of medication labels?

A. Make the pharmacy name prominent

B. Use words instead of numbers (two instead of 2)

C. Use vertical warning labels to maximize space

D. Include the indication for use

10. How can healthcare providers promote clear communication in a telemedicine patient visit?

A. Allow patients to complete visits while working or driving for their convenience

B. Use the teach-back method to ensure patient comprehension

C. Do not proceed with telemedicine visit if patient unable to connect via video

D. Offer a written summary of the visit if requested by the patient

11. Which is an example of a concern regarding use of technology by patients with limited health literacy?

A. There are no differences in technology use between patients with low or adequate health literacy

B. Most patients with low health literacy do not use technology at all to find health information

C. Patients with low health literacy are more likely to seek health information from less credible sources

D. Patients with low health literacy are more likely to use online patient portals to access their health information

12. Which of the following best defines personal health literacy?

A. The ability to read and write

B. The ability to speak the same language as one's healthcare professional

C. The ability to use information to inform health-related decisions for oneself

D. The ability to understand medical terminology and jargon

13. What tool was developed to assist pharmacists in assessing patients' medication literacy?

A. RALPH

B. REALM

C. BRIEF

D. TALKDOC

14. Medication nonadherence is associated with appropriately how much of the American population have trouble taking their medications and how many deaths per year?

A. 30% of Americans; approximately 125,000 annual deaths

B. 75% of Americans; approximately 125,000 annual deaths

C. 50% of Americans; approximately 300,000 annual deaths

D. 75% of Americans; approximately 300,000 annual deaths

15. Which of the following could be an indicator of limited pharmaceutical/medication literacy?

A. Able to explain what the warning label on their prescription means in their own words

B. Able to explain how to take their medications correctly

C. Patient does not ask questions when given conflicting information from different healthcare providers

D. Patient asks several questions about their new medication during counseling session

SELF-ASSESSMENT QUESTION-ANSWERS

1. **E**. To update and address health literacy in Healthy People 2030, Santana and colleagues provide the following definitions that address both personal and organizational health literacy. Among other key points, they incorporate a public health perspective and acknowledge that organizations have a responsibility to address health literacy as well.[2]

Personal health literacy is the degree to which individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.

Organizational health literacy is the degree to which organizations equitably enable individuals to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.

2. **A**. Two of the most widely used measures of health literacy are the Rapid Estimate of Adult Literacy in Medicine (REALM) and the Test Of Functional Health Literacy in Adults (TOFHLA). These tests are mainly used in research, but they can be used in practice.[73]

3. **D**. Most sources and studies suggest readability of health information should not exceed a 6th-grade reading level.[97–101]

4. **A**. A major barrier to consolidating data from adherence studies is that there is no generally accepted “gold standard” for measuring medication adherence, making overall conclusions difficult.

See Table e2-6 for examples of other medication adherence questions/strategies.

5. **B**. Perhaps one of the most essential components necessary to improve medication management in patients is obtaining a thorough and complete medication history. This is important for all patients regardless of their health literacy level. However, because patients with limited health literacy have difficulty naming their medications and are more likely to mismanage their medications, taking a complete baseline history of what they are taking is especially valuable.

Perhaps a key point to remember about health and medication literacy is the vital importance of proper medication counseling. The National Conference of Pharmaceutical Organizations (NCPO) agreed that appropriate counseling on the use of medications should be a key goal of healthcare reform in a 2009 policy statement, “From Reform to Revolution: Maximizing the Power of Proper Medication Use in Patient Care.”

6. **D**. A medication review can be useful in identifying patients with limited health literacy skills. If the refill history is accessible, one might find that they often forget to refill their medications on time or never pick them up. They may not be able to name or provide a list of their medications even when on just a few medications. If the medication bottles are available, the patient can be asked to state the name, use, and dosing instructions for each of their medications. Patients with limited health literacy may not be able to respond accurately. They may say, “I take them just like it says on the bottle,” or they have to look at the pill color and shape before they can respond.

7. **C**. See Table e2-2 for examples of groups at high risk of limited health literacy

8. **A**. See Table e2-3 for a literature review on effects of limited health literacy on various aspects of medication use. Decreased ability to name and identify medications has consistently been shown in multiple studies. While limited health literacy has been associated with decreased medication adherence in some studies, others have shown increased medication adherence or no effect at all.

9. **D**. See Table e2-4 for guidance on prescription labels. USP recommends the most important information for correct and safe medication use to be prominent, such as patient name, drug name and strength, and directions. Prescriber and pharmacy name can be less prominent. It is also

recommended to use numbers instead of words (2 instead of two) and to avoid vertical warning labels.

10. **B.** See Table e2-7 for clear communication tips for telemedicine visits. It is recommended for both parties to have a quiet, private place to talk. Conducting a visit while the patient is driving or at work may not allow them to focus on the visit. The teach-back method is a means of allowing the patient a chance to repeat back instructions provided and the opportunity for the healthcare provider to correct misunderstandings. While audio and visual telemedicine visits may allow for multiple teaching channels to be used, not all patients may have access to video and must interact by telephone only. Written summaries of the visit should be provided to patients regardless of whether they request it.

11. **C.** See the “Technology and Health Literacy” section, which highlights differences between patients with low and adequate health literacy with regard to use of technology.

12. **C.** See the “Introduction” section for health literacy definitions. The ability to read and write describes literacy in general. While the ability to speak the same language as one's healthcare provider and to understand medical terminology and jargon may contribute to improved understanding of health information, health literacy also involves using information gathered to inform health-related decisions.

13. **A**. The Recognize and Address Limited Pharmaceutical Literacy Skills (RALPH) interview guide was developed to assist pharmacists in assessing patients’ medication literacy, or their ability to understand and apply instructions for safe and effective medication use, during a typical patient counseling session.[79]

14. **B**. Table e2-3 shows that the current evidence for the association between health literacy and medication adherence is inconclusive. However, available data indicate that medication adherence is challenging to many people nationwide; an estimated 75% of Americans have trouble taking their medicine as directed; approximately 125,000 annual deaths result from nonadherence to medications. Indeed, poor adherence is a major public health challenge, and it is logical that people with low health literacy likely have even a bigger challenge.

15. **C.** See RALPH Interview Guide for indications of limited pharmaceutical literacy. A patient's ability to explain how to safety and correctly take medications in their own words would indicate adequate health literacy. While a patient with limited pharmaceutical literacy may have more medication-related knowledge gaps, asking several questions about a new medication is not an indicator on its own. Rather, it would indicate adequate pharmaceutical literacy since the patient would be seeking medication information from a reliable source (the healthcare provider). A patient who does not ask questions or seek clarification despite receiving conflicting information from different healthcare providers is more likely to have limited pharmaceutical literacy.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e

Chapter e3: Exploring Cultural Diversity and Equity in Healthcare

Amanda M. Loya; Jeri J. Sias; Lakesha Butler; Christopher G. Medlin; Jessica M. Shenberger-Trujillo

KEY CONCEPTS

KEY CONCEPTS

① Healthcare providers should strive toward cultural competency and equity in the context of social determinants of health and community history to improve care and access unique resources for patients and communities from diverse cultures and backgrounds.

② Changes in demographics in the United States, health disparities, patient safety, and healthcare workforce shortages are among the reasons for needing cultural and linguistic competency skills and for promoting diversity and equity in healthcare.

③ A variety of models recognize cultural competency as a process, not an achievement.

④ Legal and regulatory issues surrounding cultural competency include understanding and interpreting accreditation standards for healthcare organizations and Title VI of the Civil Rights Act.

⑤ Patients may enter the healthcare setting with a different explanation of their illnesses than what is found in the Western biomedical model (WBM).

⑥ Cultural values and beliefs influence decisions and attitudes about healthcare, including race, ethnicity, age, gender, sexual orientation, and religious beliefs.

⑦ Developing communication skills to interact with diverse populations involves recognizing personal styles and cultural values of communication as well as barriers to patient understanding.

⑧ Linguistic competency encompasses understanding the capacity of organizations and providers to communicate well with diverse populations such as patients with limited English proficiency (LEP), low literacy, or hearing impairments.

⑨ Before practitioners can understand other cultures, they should strive to understand the personal and organizational values and beliefs.

⑩ Skills for working with patients from diverse cultures include being able to listen to the patient's perception of health, acknowledging differences, being respectful, and negotiating treatment options.

BEYOND THE BOOK

BEYOND THE BOOK

Select any one of the patients from diverse backgrounds from the cases introduced in the first section of this chapter. What are the factors that influence their health that are based on genetics? Individual and family choices? Community influences? Larger city and policy structures?

For more in-depth discussions, consider these activities and questions:

1. Use Healthy People 2030 to identify Social Determinants of Health found in the cases.
2. Describe what you think would be the acculturation of each patient. What is the host culture? What is the home culture?
3. Explore values and beliefs found in resources provided in the chapter: Based on the information provided, what social identity and acculturation characteristics are involved? Look up information about healthcare beliefs and values based on how the patient self-identifies with religion and race or ethnicity.
4. Discuss what you would describe to be your own “cultural competency” to work with each of the patients. Which models do you prefer?
5. If approached by one of the patients, providers may argue that “we can’t solve everything in healthcare. I only have so much time during a visit.” How might you respond to those statements? What changes can be made at a provider level, clinic/hospital level, and at a larger system-wide level to improve care across cultures?

CULTURE, COMMUNITY, AND SOCIAL DETERMINANTS OF HEALTH

Culture influences who we are, including our thoughts, behaviors, and beliefs toward healthcare. What is culture? **Culture** can be defined as “the learned and shared beliefs, feelings, and knowledge that individuals and/or groups use to guide their behavior and define their reality as they interact with the world.”[1,2]

Social determinants of health are also of great influence, and unlike a person’s genetic makeup, which is largely nonmodifiable, social determinants of health can be addressed. Determinants of health describe the factors that affect a wide range of outcomes and risks associated with the quality of life, functioning, and health of individuals (Fig. e3-1). Each person’s health outcomes are influenced by factors based on the places where they live, work, worship, or play and their structural environment (eg, sidewalks, exposure to clean air, access to quality education and healthcare, social norms, and attitudes such as racism and discrimination).[3] According to the Robert Wood Johnson Foundation County Health Rankings, individual lifestyle choices comprise approximately 20% of the determinants of health outcomes; clinical care also makes up 20%, while social and economic factors (40%) in addition to physical environment (10%) make up half of the factors influencing health outcomes.[4] Basically, our identities such as socioeconomic status, race and ethnicity, gender, age, and environments, as part of our cultures, shape us and can play a major role in our overall health status.[5]

Consider the following brief descriptions of three individuals and the determinants of health that influence them.

> *Patient 1 is a 42-year-old bilingual Vietnamese American, Buddhist woman living on the West Coast whose family immigrated to the United States 35 years ago. Her lifestyle choices include a vegetarian diet, gardening, and daily meditation. She lives in a suburban community with her husband and three children, drives a hybrid electric/gas car to her work as a schoolteacher and purchases food from a local farmer's market. She has health insurance, and her city public policy includes no indoor smoking in public places and state policies include special low-emission requirements on vehicles. Weekend activities with the family include sports and dance for the kids along with others from the community center that serves several Asian American families.*
>
> *Patient 2 is a 27-year-old single African American, Muslim upper-middle-class man living in a major city in the Eastern Coast of the United States. Having just finished his graduate school degree, he lives in a high-rise apartment and walks or rides the subway to his work at a major corporation. In his leisure time, he enjoys reading and going to major sporting events with his college friends who come from diverse backgrounds. During the week, he also frequents the local mosque and community events that are supported by his neighborhood.*
>
> *Patient 3 is a 55-year-old European American, Protestant middle class man living in the Midwest. He identifies as gay and is in a monogamous relationship with his partner for 5 years. Due to recent economic changes in the community, he now must work three part-time jobs (two in food industry and one in construction) so that he can help support his partner who is undergoing cancer treatment for lymphoma. As a result of his high work demands, he is not able to shop for groceries or exercise and so the couple often eats away from the home, or they prepare quick and processed meals at home. He notices that he has gained about 10 pounds (4.5 kg) in the past 6 months and has difficulty sleeping. The family also has not had time to connect with their church or other friends due to his work and doctor appointments for his partner.*

Can healthcare professionals assume that these three patients have the same healthcare beliefs, values, and approach to healthcare? While each of the patients described above will have a unique health situation, social determinants will influence their exposure to health disparities or inequities and their cultural backgrounds will also shape their health beliefs and behaviors.[6]

As healthcare organizations and practitioners seek ways to improve health equity and quality across populations, they can develop their cultural and linguistic competencies. To engage with and serve patients from diverse cultures, each healthcare practitioner should have **cultural humility,** or be a part of a "lifelong process of self-reflection and discovery to understand one's own culture as well as another's culture, by starting with a critique of his/her/their own beliefs and cultural identities."[7]

Cultural competency may be described as the attitudes, knowledge, skills, and values that an individual has and uses in working effectively in a cross-cultural environment.[8,9] At an organizational level, cultural competency can be demonstrated by an organization having a defined set of values and principles (mission), policies, and structures for service delivery that incorporate community input and enable individuals in the organization to work effectively within cultures and cross-culturally.[2,8]

Linguistic competency is linked to cultural competency. It describes the "capacity of an organization and its personnel to communicate effectively and convey information in a manner that is easily understood by diverse audiences" (eg, persons of LEP, those who have low literacy skills, individuals with different hearing or sight abilities).[9]

The environments we live in—our communities—also define our health.[5,6,10] Research suggests that while we should address health at the individual level, providers and policymakers must also understand and address healthcare at the community and population level.[11,12] But what creates a community? **Communities** may be defined as organized groups of people with a shared identity that *may exist around* racial and ethnic groups, socioeconomic position, religion, age, gender, language, as well as other cultural ties.[13] Communities can also cut across these variables. **Community competency** encompasses cultural competency; however, it also recognizes the unique role of communities as a type of culture.[13] Within a community competency framework, clinicians will understand that at the core of a community are ***history, context, geography, and culture***.[13] For example, given similar socioeconomic and educational backgrounds, an adolescent male raised in Chicago, Illinois, whose family is from Puerto Rico would have a different life experience (ie, a different community or environmental influence) than an adolescent male of a similar family background being raised in Greenville, South Carolina.

History helps describe the collective consciousness of a community. For example, a community's recent history may include the devastation of a flood or tornado. Political history can affect a refugee population's experience and the history of slavery in the United States affects multiple communities. The history of a community is not always considered in social determinants of health models but understanding the history can enhance evaluating the social determinants of health. ***Context*** acknowledges the present situation of a community such as the quality of education, housing, or healthcare. ***Geography*** helps to distinguish differences between a male of Islamic religion and Somali descent who is raised in Philadelphia, Pennsylvania, from one who is raised in St. Paul, Minnesota.

What is the difference between cultural and community competency? Cultural competency helps clinicians understand the individual; thus, "culturally competent care can be considered patient-centered care."[13,14] Community competency provides a broader context for clinicians to work with individuals and families, as it incorporates the influence of the population and environment on the individual. Although this chapter focuses on cultural competency and care of individuals, acknowledging the influence of community on individuals is significant.

① Healthcare providers should strive toward cultural competency and equity in the context of social determinants of health and community history to improve care and access unique resources for patients and communities from diverse cultures and backgrounds. This skill is increasingly important to healthcare practice as our society becomes more and more diverse. The healthcare provider tries to negotiate an approach to treatment that is respectful of patient beliefs, while integrating an effective course of therapy in a manner consistent with the patient's beliefs and understanding. This approach does not devalue the patient's cultural and community beliefs. As a result, better treatment adherence can occur.[15] The negotiation between provider and patient is the art of patient care and is a skill that requires continual practice.

A more culturally competent approach to care integrates—at all levels—the importance of culture, the assessment of cross-cultural relations, vigilance toward the dynamics that result from cultural differences, the expansion of cultural knowledge, and the adaptation of services to culturally unique needs of the patient.[2,8,15] In short, there is respectful acknowledgment of the patient's belief system. A culturally competent approach to care includes a set of behaviors and attitudes that enable a healthcare provider to work effectively in cross-cultural situations with humility, sensitivity, and cultural awareness.

Reasons for Cultural Competency and Promoting Diversity in Healthcare

② Changes in demographics, health disparities, patient safety, and healthcare workforce shortages are among the reasons for needing cultural and linguistic competency skills and promoting diversity and equity in healthcare.[15] In this section, the situation as it exists in the United States is detailed. The central concepts would be similar for other countries around the world, even though some of the specifics would vary.

The United States is diverse.[16] Approximately 42% of the population identifies as Black or African American, Hispanic, Asian, American Indian, being of another race that is not White, or as coming from two or more races.[16] The United States is aging, with 16.5% of the population reported as being 65 years of age or older.[16] Furthermore, people have diverse religions, languages, and countries of origin. Nearly 75% of adults in the United States report identifying with a particular faith or religious group.[17] At least 350 distinct languages are spoken in US homes.[18] The three patients described in the beginning of this chapter highlight some of the diversity that might be encountered throughout United States.

Regrettably, health disparities generally occur in populations who have systematically experienced a social, economic, or environmental disadvantage in society. While disparities are often linked to differences in race and cultural backgrounds, they also exist among groups based on religion, ability status, sexual orientation, and age, among other characteristics. **Health disparities** refer to gaps in the quality of health and healthcare and can include differences in rates of disease or illness, access to healthcare, or general health outcomes.[19] One of the overarching goals of Healthy People 2030 (Table e3-1), which frames the national health agenda, is to eliminate health disparities that exist in our population and achieve health equity.[3]

TABLE e3-1

Overarching Goals of Healthy People 2030

- Attain healthy, thriving lives and well-being free of preventable disease, disability, injury, and premature death.
- Eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all.
- Create social, physical, and economic environments that promote attaining the full potential for health and well-being for all.
- Promote healthy development, healthy behaviors, and well-being across all life stages.
- Engage leadership, key constituents, and the public across multiple sectors to take action and design policies that improve the health and well-being of all.

Data from US Department of Health and Human Services, July 14, 2021.

Health disparities may vary based on the population and the health outcome measured. For example, adults in the United States who are African American experience higher mortality rates of heart disease compared to non-Hispanic Whites.[20] Diabetes prevalence rates are greater among adults with lower household incomes, Hispanics, and African Americans than among Asians and non-Hispanic Whites. Suicide rates are higher among men than women, with elevated rates found in American Indians/Alaska Natives as well as Lesbian, Gay, Bisexual, and Transgender (LGBT) youth.[21,22] Smoking prevalence is higher among adults who have not graduated from high school when compared with adults with a college degree.[23] These statistics and others like them underscore the need for improvements in the quality of healthcare for historically marginalized groups.

Health disparities or inequities persist due to existing social determinants of health that result from both historical and contemporary discrimination and structural barriers in society. Disparities in physical environment, social, and economic factors exist in racial/ethnic minority groups. These differences are rooted in structural racism in the society and nation that originated hundreds of years ago and is still experienced present-day.

Structural racism is the normalization and legitimization of historical, cultural, institutional and interpersonal dynamics that, in the United States, have routinely led to advantages among White populations while producing cumulative and chronic adverse outcomes for people and communities of color.[24] Minorities have been subjected to marginalization within society in forms ranging from genocide and slavery to exclusionary policies and practices that continue today.

Segregated neighborhoods resulted in lack of generated wealth and greater exposure to environmental pollution for minorities, increasing their likelihood of pulmonary conditions and lower life expectancy. These under-resourced neighborhoods also have under-resourced schools, limited access to hospitals, physicians, and pharmacists, and limited healthy food options. Discrimination in the workplace, healthcare, and society can result in racial/ethnic minority individuals receiving subpar healthcare, job opportunities, higher education and can overall result in greater stress and trauma, putting patients at greater risk for disease states such as hypertension and heart disease.

Because of societal and cultural norms in the United States, some individuals are treated differently and unfairly based on their physical characteristics. This unfavorable treatment can be referred to as **explicit (conscious) or implicit (unconscious) bias**.[25] Bias is a prejudice in favor of or against a person or group compared to another, usually in an unfair way. Our biases and prejudices can be shaped by our socialization,[26] which is the process of being exposed or taught (whether overtly or covertly) societal norms and consciously or unconsciously using this information to guide our behaviors and beliefs.[25,27] Implicit biases can contribute to health disparities, affect the patient-provider relationship, contribute to patients' lack of trust, and decrease overall patient health outcomes.

A healthcare provider's cultural competency can help to address health disparities in their communities and empower patients from minority groups to improve their health.[28,29] By understanding the needs of underserved patients and by identifying the unique resources available within these populations, the healthcare provider can positively impact patient's healthcare experience. For example, a healthcare provider who understands the importance of community support in a Latino patient seeking healthcare can include a key community member (eg, a *promotora* or community health worker) as an active advocate for prevention measures, treatment, or posttreatment care.[30,31] By working within the patient's cultural needs and expectations, the provider can use otherwise overlooked support systems (eg, family, neighborhood friends, and religious ties) in a community with fewer or overtaxed resources. Using cultural competency skills to better identify cultural and community assets in minority and underserved populations allows the provider to go beyond basic awareness of and sensitivity to cultural differences to increase a patient's adherence with treatment and positively impact patient health outcomes.[32] Additionally, the provider's ability to empower patients through cultural competency will facilitate the development of trusting patient/community/provider relationships.[33]

Culture and language may also play a role in patient safety.[34] Errors and adverse events can occur because of differences in language between healthcare providers and patients, ineffective use of an interpreter, or inadequate translation of written material related to health. Poor judgment or lack of adherence to a treatment plan can occur because of discordance in a patient's cultural health belief system. Cultural "incongruences" among patients and providers may lead to making judgments about a patient's decision to use complementary and alternative medicine (CAM) or casting stereotypes based on personal biases about healthcare.[14]

While some areas of the country may have a surplus of providers, there are still shortages in healthcare providers across disciplines as well as lack of diversity among providers, which contributes to health disparities.[35] More than 65 million Americans live in areas that are designated by the Health Resources and Services Administration (HRSA) as primary care health professional shortage areas.[36,37]

To meet the healthcare needs of a multicultural society, there is a compelling need to equip current and new providers with the skills to provide a culturally competent approach to care. The education and recruitment of a culturally diverse workforce can lead to greater provider-patient concordance (ie, ability for a patient to consult with a provider of similar cultural or linguistic background).[37,38]

Given the dynamic shifts in demographics in the United States and contrasts in health equity across cultures, healthcare providers cannot ignore the effects of culture on healthcare. If the healthcare system does not acknowledge and address cultural influences in patient care, patient safety can be compromised. Opportunities exist for educating providers and recruiting a more diverse workforce to care for society.

CULTURAL COMPETENCY MODELS

③ Several models have been used in healthcare to describe and understand cultural competency: the Cultural Competence Continuum by Terry Cross, the Purnell Model for Cultural Competence by Larry Purnell, and the Process of Cultural Competence in Delivery of Healthcare Services by Josepha Campinha-Bacote.[39–41] Across these models, a salient theme surfaces—cultural competency is a process rather than an achievement.[39–41] As practitioners participate in a lifetime process of development, employing cultural humility, and not making assumptions about their own skills can be helpful for working across cultures.[7]

In the **Cross Cultural Competence Continuum**, six stages are described in a stepladder model starting with cultural destructiveness and ascending toward cultural proficiency.[40] *Cultural destructiveness* in healthcare occurs when a person or an organization actively devalues or berates patients or a community based on their cultural background (eg, race, language, and religion). When persons or organizations are willing but unable to support culturally oriented practices, they demonstrate *cultural incapacity*. *Cultural blindness* results from an effort to treat every patient or family the same regardless of culture. However, the provider or organization can miss key elements in the patient's healthcare behavior that are attributable to their culture. Treating patients equally does not necessarily signify that patients should be treated the same. In *cultural precompetency*, individuals and organizational leaders recognize that culture is influential in healthcare and efforts are made to improve and adapt care related to culture. In this stage, providers and organizations often believe that making a few adjustments or changes in practice or policy to improve care to diverse cultures are sufficient. However, they do not embark on a continuous improvement plan.

Although cultural competency can really never be achieved, individuals and organizations demonstrating traits of *cultural competency* will value diversity and seek to continuously implement and evaluate new ideas and programs to improve their care to patients and families from different cultures. Those providers and organizations considered to be more *culturally proficient* will be viewed as leaders at the forefront of cultural competency who are actively educating others or conducting research in the field.

The **Purnell model** explores the relationship of family, community, and the global society as they influence the individual person.[39] The model further outlines 12 different cultural beliefs and traits that may affect the individual and are often interconnected, such as healthcare practices, spirituality, communication styles, and workforce issues. In this model, Purnell illustrates that healthcare providers and organizational leaders often experience a learning process related to their cultural consciousness. In this continuum, providers may move from being unconsciously incompetent (not aware of lack of competence), consciously incompetent (aware of lack of competence), consciously competent (aware of improving competence) toward unconscious competence. When a provider is unconsciously competent, they have been able to integrate skills, knowledge, and awareness of the varying cultural, familial, and broader community influences on a patient with fluency.

In the **Campinha-Bacote model**, five constructs with an interdependent relationship describe the development of a process of cultural competence infused with cultural humility: cultural awareness, cultural knowledge, cultural skill, cultural encounters, and cultural desire.[42] Cutting across all of these constructs is a sense of *cultural humility,* where practitioners have an understanding of social inequalities while demonstrating a deep and genuine commitment to kindness and social justice. By self-assessment of cultural and professional biases and beliefs, clinicians develop increased *cultural awareness*. This self-awareness helps clinicians to recognize the risk of imposing personal beliefs in patient care. As clinicians learn more about beliefs and practice, disease epidemiology, and the efficacy and acceptance of therapies that are found in diverse cultures, they expand their *cultural knowledge*. Providers acquire *cultural skills* as they learn how to collect subjective information and social histories as well as conduct physical assessments that are relevant to different cultures. The increased opportunity for *cultural encounters* through directly interacting with individuals and families from diverse groups helps providers to have practical experience with cultural norms and variations as well as language needs. At the intersection of awareness, knowledge, skills, and encounters is cultural desire. When providers want to learn and grow in the process of cultural competency and do not feel obligated to care for diverse cultures, then they expand their *cultural desire*. Throughout these processes, providers recognize the continuous process of learning.

As clinicians use these models and work with new cultures and in new environments, they may feel that they regress and are not as competent. However, if organizations and clinicians recognize that they are on a path of continuous improvement and approach the care of patients and communities with an attitude of humility and sensitivity to potential opportunities and barriers in care, they will be taking great strides toward providing a positive healthcare environment for their patients and the communities they serve.

LEGAL, REGULATORY, AND ACCREDITATION REQUIREMENTS

④ Legal and regulatory issues surrounding cultural competency include understanding and interpreting Title VI of the Civil Rights Act and accreditation standards for healthcare organizations. Title VI "prohibits discrimination on the basis of race, color, and national origin in programs and activities receiving federal financial assistance."[43,44] In 2000, under Executive Order 13166 of Title VI, federal agencies were required to evaluate and develop services for persons with LEP and meaningful access to these services.[44,45]

The 2013 enhanced National CLAS Standards (Culturally and Linguistically Appropriate Services) provide a framework for health and healthcare organizations to promote health equity and quality for diverse populations.[46] The Standards open with an overarching principle to "provide effective, equitable, understandable, and respectful quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs." Fourteen additional standards grouped in three themes provide further guidance, including: (a) Governance, Leadership and Workforce (Standards 2-4); (b) Communication and Language Assistance (Standards 5-8); and (c) Engagement, Continuous Improvement, and Accountability (Standards 9-15). State and national policies have provided particular emphasis on access to language services including interpreters.[44,45] Standards 5 through 9 are federally mandated and must be offered and/or provided by agencies receiving federal funding (Table e3-2). Challenges persist to appropriately use, certify, and reimburse professional interpreters with a growing number of states also requiring cultural competency training for health professionals.

TABLE e3-2

Select Communication and Language Assistance Standards for Culturally and Linguistically Appropriate Services (CLAS) in Health and Healthcare

Standard 5: Offer language assistance to individuals who have limited English proficiency and/or other communication needs, at no cost to them, to facilitate timely access to all healthcare and services.
Standard 6: Inform all individuals of the availability of language assistance services clearly and in their preferred language, verbally and in writing.
Standard 7: Ensure the competence of individuals providing language assistance, recognizing that the use of untrained individuals and/or minors as interpreters should be avoided.
Standard 8: Provide easy-to-understand print and multimedia materials and signage in the languages commonly used by the populations in the service area.

Data from Reference 44.

The Joint Commission (TJC), the primary national accrediting body for healthcare organizations and programs, supports CLAS standards through requirements for effective communication, cultural competence, and patient-oriented care.[47] This roadmap highlights the importance of integrating culturally competent care across the organizational and professional structure from patient admission to dismissal. Further, TJC has developed field guides to address care in the LGBT communities as well as evaluate safety based on the potential for implicit bias in healthcare.[48]

Improved patient safety occurs when providing appropriate language services and obtaining informed consent with well-translated and easily understandable forms. Thus, TJC has recommendations based on cultural and linguistic competency.[34,47] Considerations include collecting patient-level demographic data to report outcomes to better understand patterns in health disparities. HRSA has also developed indicators of cultural competence in healthcare organizations. The incorporation of cultural competency into TJC standards and HRSA guidelines gives organizations and healthcare leaders further rationale to move toward more culturally competent care.

TJC also emphasizes leadership involvement and ongoing staff education related to cultural competency. Further, more than 30 states in the United States have passed legislation requiring healthcare professionals to complete training in cultural competency or multiculturalism and/or have state-sponsored implementation activities.[46,49]

The healthcare system must work to engage patients and their communities.[5] There are definite trends from stakeholders in managed care, government, and academia to incorporate cultural competence for the purpose of improving quality of care and in some cases as a business imperative.[50] Independent of the legal and regulatory requirements, the ultimate goal of a healthcare provider is to improve patient outcomes including understanding the culture and language of patients.

PATIENT EXPLANATORY MODEL (PEM)

⑤ How do patients experience and understand their own health? According to medical sociologists, patients may enter the healthcare setting with a different explanation of their illness than the explanation found in the **WBM**. This model proposes that there is a pathophysiologic or etiologic reason for a disease. In many cultures, the source and meaning of illness may be attributed to a variety of other causes such as spiritual or religious influences or to retribution for previous deeds.[51] The term **disease**, from the view of Western medicine, is the result of a physiologic process. However, in most of the world cultures, the concept of **illness** is intimately related to the spiritual or religious aspects of their respective society. The clash of cultures can sometimes cause confusion in the patient and/or the provider about the true effects of a treatment or illness. This conflict can cause unfortunate outcomes on many levels. To help identify cultural differences in a clinical setting, providers can ask patients questions to help elucidate the previous unforeseen differences.

One of the most studied and widely used clinical models is the PEM. It includes eight questions to evaluate a patient's explanation of disease (Table e3-3).[52] The model may best be used when clinicians sense discordance with the patient relating to adherence to a treatment plan or to the overall visit (see the Clinical Presentation box for an example of how to use the PEM).[53]

TABLE e3-3

Patient Explanatory Model—Eight Questions to Elicit Patient Understanding

1. **What** do you think has **caused** your problem?
2. **Why** do you think it **started** when it did?
3. **What** do you think your **sickness does to you**?
4. **How severe** is your sickness? Will it have a short or long course?
5. **What kind of treatment** do you think you should receive?
6. **What** are the most important **results** you hope to receive from this treatment?
7. **What** are the **chief problems** your sickness has caused for you?
8. **What** do you **fear** most about your sickness?

Data from Reference 52.

CLINICAL PRESENTATION

Using the Patient Explanatory Model Versus the Western Biomedical Model

A 55-year-old Latin American woman presents to the clinic for smoking cessation therapy. She reports smoking about 15 cigarettes a day, mostly when she is stressed and depressed. She lives in a rural, primarily Spanish-speaking community. Her education is limited to the fifth grade. In her home life, she is not able to make many financial decisions without permission from her husband.

When asked questions using Kleinman's PEM, the patient may have responded as follows (*assumptions/explanations according to the WBM are included for comparison*). Review of the possible responses to the questions provides a healthcare provider with insight about how a disconnect can occur with patients or their family members in developing a treatment plan.

1. **What do you think caused your problem (smoking)?**

   PEM: Well, my blood sugar is high because I smoke.

   WBM: The patient has come in for smoking cessation with no mention of diabetes.

2. **Why do you think it started when it did?**

   PEM: My mother was sick and she passed away about 10 years ago. I started smoking then because of the stress. Right after that, the doctor told me I had diabetes.

   WBM: Type 2 diabetes onset can begin with a number of risk factors including family history and obesity. Tobacco use is a dependence disorder.

3. **What do you think your sickness does to you?**

   PEM: Smoking makes my blood sugar high. That's why I can't control my diabetes.

   WBM: Smoking can affect diabetes, but it also can lead to heart disease, lung disease, cancer, and a number of other comorbidities.

4. **How severe is your sickness? Will it have a short or long course?**

    PEM: My diabetes will not go away unless I quit smoking.

    WBM: Diabetes will continue lifetime. Smoking cessation can occur, and if maintained, a person can continue tobacco free for the remainder of their lifetime.

5. **What kind of treatment do you think you should receive?**

    PEM: If I quit smoking, my diabetes will go away. I will use the patch and gum like you told me. I know I can't pay for the other medicines.

    WBM: To quit smoking, the patient may incorporate behavioral support with nicotine products. With depression, bupropion may also be indicated. The diabetes will require different medications as well as lifestyle support for diet and exercise.

6. **What are the most important results you hope to receive from this treatment?**

    PEM: That my diabetes will go away.

    WBM: That her general health will improve with smoking cessation. We can support improvement in her diabetes control.

7. **What are the chief problems her sickness has caused for her?**

    PEM: Smoking costs a lot of money, but I can buy cheaper cigarettes in Mexico. I am tired a lot.

    WBM: She may not feel the effects of smoking and may actually feel less anxious. However, lack of control of blood sugar can cause fatigue, frequent urination.

8. **What do you fear most about her sickness?**

    PEM: That I will die soon, like my mother.

    WBM: That smoking can lead to heart disease, lung disease, and cancer. The diabetes can also lead to negative health consequences and poor quality of life.

A modification of the PEM is the "4 Cs" (Call, Cause, Coping, Concerns), and this mnemonic device may be useful for providers.[14] Providers may ask the patient: (1) "What do you *call* the illness?" (2) "What do you think *caused* the disease or illness?" (3) "How do you *cope* with the disease or illness?" and (4) "What *concerns* do you have about your disease or illness?" This simplified version of Kleinman's original questions still provides information about how the patient interprets illness. However, use of the full explanatory model can provide more revealing information.

CULTURAL VALUES AND BELIEFS

⑥ Numerous factors can influence cultural values and beliefs toward healthcare as suggested by social determinants of health. Age, gender, race, ethnicity, sexual orientation, religion, geography, neighborhood, acculturation, and linguistic identities all shape how people behave and what they value. One of the dangers of learning to work with patients and families from different cultures is confusing stereotypes with generalizations. **Stereotypes** may be damaging to patients as they are an end point or assumption about the way people will behave.[14] **Generalizations**, however, can provide a framework or a beginning to understand how patients *may* respond in healthcare situations.[14] When developing a framework to work with patients, understanding the degree to which individuals identify themselves within different cultures is worthy of consideration.

Social Identity

One aspect of culture is linked to how social identity is defined. **Social identity** is a socially constructed characteristic shared by a group of people which sets them apart from other groups.[54,55] Social group identities can be based on gender, gender identity, age, ethnicity, race, sexual orientation, religion, socioeconomic status, ability status, or other cultural factors. Individuals' social identities can either be classified as **agent, border, or target** based on cultural norms.[54,55] An **agent** is an individual who belongs to **social identity** groups that have ready access to resources resulting in social power and privilege.[54,55] Agent identity examples include heterosexual orientation, Christian religion, upper socioeconomic class, White race, and middle-aged adult. **Target identity groups** consist of individuals who are denied access to resources, resulting in less or no **social power.**[54,55] **Target** identity groups include people of color, lower class, homosexual orientation, youth or older adults. **Border identity groups** may or may not have been privileged in the past, or who have privilege in some contexts and are **targeted** in other contexts.[54,55] Members of this group may be able to "pass" as members of the **agent** group. Examples include biracial individuals, those with a hidden disability and the middle socioeconomic class. An individual's social identities can influence their acceptance and hierarchical position as either superior or inferior according to societal and cultural norms.[54,55]

An individual's identification with a social group is influenced by contextual factors, such as individuals within the immediate environment.[56] For example, an African American woman may identify more strongly with her gender identity in the presence of several African American males but identify more strongly with her racial identity in the presence of several White women. In other words, there are instances in which one social group membership may become more salient and thus be more influential on behaviors than other group memberships. Understanding how strongly a patient identifies with a particular social group will assist healthcare providers in identifying the influence of that social group's cultural norms and expectations on the patient's healthcare decision-making. For example, a patient who has recently immigrated must redefine how they identify with cultural groups or if they are considered target, agent, or border in the new context. This, in turn, defines how individuals experience the process of acculturation within dominant cultural groups in a new host country.

Acculturation

Culturally competent providers are familiar with the concept of acculturation and its role in the area of health. **Acculturation** can be defined as the process by which individuals from one cultural group experience changes in behaviors, attitudes, and beliefs as a result of continuous contact with a different culture.[56] Acculturation has been studied in relation to a number of health behaviors and its influence cannot be underestimated.[57]

Acculturation has been associated with a number of differences in health behaviors and perceptions of illness. For example, a patient may present with unique behaviors for willingness to use healthcare, adherence, attitudes toward healthcare providers and treatment, or beliefs about healing.[58] Some weaknesses in theories of acculturation (in studies conducted in the United States) exist because assumptions are made that immigrant populations are able to choose to participate fully in American society and that the ultimate goal is to assimilate into American culture.[12]

Regardless of how acculturation is measured or researched, understanding concepts related to acculturation can be helpful to providers. One model of acculturation that provides a framework for understanding acculturation describes assimilation, integration, marginalization, and separation as four possible outcomes of the acculturation process. In this framework, there are two cultures of reference, the home culture (the culture *from* which the individual comes) and the host culture (the culture *to* which the individual is introduced or is immersed).[57,59] This relationship can have varying levels of effect on each other and can be bidirectional in nature.

Individuals may have the least difficulty adapting to the new host culture when they are able to assimilate or integrate.[57,59] In **assimilation**, individuals lose (willingly or unwillingly) much of their identity from their home culture and adopt the new host culture. In **integration**, the individual is able to adopt identities from both the host and home culture. These individuals may be considered bicultural or even bilingual.

Through the process of marginalization and separation, individuals have a more difficult time adapting to a new host culture.[57,59] When individuals are **marginalized**, they have strong identities to their home culture and may not be able to adapt well to the host culture. Marginalized individuals may include more recent immigrants or refugees. Persons who are in **separation** may never really understand their home culture or their host culture. They may live "in between" cultures, never fully learning the home culture or host culture. This phenomenon may occur in children who have never completed their basic education in either culture (thereby never mastering one language) or who do not have enough exposure to cultural events and traditions from their home or host culture to entirely understand or appreciate either heritage.

As healthcare providers interact with patients, recognizing influences of acculturation can be helpful to understanding acceptance of prevention and treatment options.

Individual Versus Collective Influences

There are other factors that influence how persons interact in cultures. For example, different cultures place varying emphasis on the importance of the individual and the collective influences on decision-making.[60] Those persons who come from more **individualistic cultures** (eg, the United States) are more likely to place greater emphasis on an individual's self-reliance and emotional distance from others within the individual's group.[61] Patients from individualistic cultures expect greater individual responsibility for healthcare decisions.[62]

Alternatively, persons who come from **collective cultures** experience greater emphasis on interdependence and family integrity.[61] Patients from collectivist cultures experience increased community participation with their healthcare decision-making.[63] Some cultural groups (eg, Latino, African American, and American Indian) may identify as being particularly **familistic**—the family unit has a core influence on their cultural and community identity.[64] A greater emphasis on the family unit leads to different attitudes and behaviors such as different expectations for seeking healthcare (eg, an aunt or godmother caring for the ill) and the development of different beliefs, norms, and traditions.[65]

Health Beliefs and Practices Found in Various Cultures

As healthcare providers work with patients from different cultures and backgrounds, they will discover healthcare beliefs and practices that are different from their own. Although it is not feasible to understand the intricacies of every culture, it is possible to explore common characteristics that are found in various cultures in order to learn more about them. Ultimately, **care should be individualized,** but **the following generalizations can serve as a guide to working with patients from different cultural backgrounds**. In some cases, clinicians can apply the mantra, "Treat others as *they* would want to be treated," also called the *Platinum Rule*.[58]

Individuals from different cultures may have different beliefs about the origins of health and illness and may not subscribe to the WBM.[38,52] Some cultures may view health as the result of harmony with nature or the balance of natural forces. Still others may believe that health is a result of good luck or reward for good behavior. Views about the origins of illness may also differ depending on culture. Some believe that illness is the result of an imbalance in natural forces while members of other cultures may point to supernatural powers as the cause of disease or illness. Various cultures describe illnesses that are only recognized within that culture. These "culture-bound syndromes," also often referred to as folk-illnesses, are often manifested through changes in behavior, cognition or affect without the presence of signs or symptoms that can be objectively confirmed.[14,66] There are a variety of culture-bound syndromes that have been documented. For example, conditions such as *empacho* (stomach pain caused by ball of food blocking the digestive tract), *susto* (illness arising from extreme fright), *mal de ojo* (illness caused by the "evil eye" resulting from excessive admiration or envy), or *caída de la mollera* (depression of anterior fontanelle in infant) can be found in Latin American cultures.[39,51] *Dhat* is a culture-bound syndrome reported in Indian cultures that manifests as fatigue, weakness, or sexual dysfunction thought to be caused by loss of semen during urination, masturbation, or nocturnal emission.[67] Culture-bound syndromes are also found in Western cultures. Anorexia nervosa, an eating disorder characterized by extreme weight-loss caused by self-starvation, is well-recognized in Western cultures but may not be acknowledged in other cultures.[68]

Certain healthcare practices may stem from historical events or experiences not explained by the WBM. For example, members of minority populations who have experienced racism, prejudices, and injustices, such as African Americans, may not trust the healthcare system or participate in research projects because of previous injustices, including slavery and the Tuskegee syphilis study.[69] The latter example refers to research conducted by the United States Public Health Service from 1932 to 1972, in which African American men with syphilis were recruited to participate in a study to investigate the natural course of untreated disease.[69] This project continued until the early 1970s despite the availability of penicillin and confirmation in the 1940s that penicillin was an effective treatment for syphilis.

It is important to recognize that members of various cultures may employ the use of traditional healers, CAM practices such as the use of herbs or other practices such as massage. Traditional healers who may be involved in the care of a patient include *curanderos(as)* in some Latin American cultures, "medicine men or women" in various American Indian communities, voodoo doctors by individuals practicing voodoo, or *santeros* (mediums) among individuals practicing *Santería*, (a polytheistic religion based on beliefs and customs of the Yoruban people with incorporation of some elements of Catholicism).[39,51]

Furthermore, religious rituals or ceremonies are often an important part of treatment in many cultures. Some American Indian cultures, for example, may practice divination (diagnosis) or singing in the treatment of illness. Three types of divination include *motion in the hand* (pollen or sand is sprinkled around the patient while song is sung and diagnostician moves hand to determine the cause), *stargazing* (prayer to star spirit is made by stargazer and rays of light thrown by star are used to determine cause of illness), and *listening* (diagnostician listens for certain sounds to help in diagnosis). For some members of American Indian cultures, these practices may have a profound psychologic effect and allow the patient to feel cared for in a personal way.[51] Patients from various religious backgrounds may also include prayer as a way of coping with life stresses.[70]

Other culturally based healthcare practices may lead to physical signs on the body that might be taken as signs of injury or abuse. Patients of Asian descent may practice *coining* (coins are dipped in oil and heated and then rubbed on skin), *cupping* (heated glass cups are placed on the skin to create vacuum), *moxibustion* (heated incenses or wood applied over the skin) or pinching of skin in order to draw out illnesses. These practices may produce bruises, burns, or welts on the skin that might be confused with signs of physical abuse.[51] Clinicians should be aware that cultural beliefs may have led to the practice of alternative forms of healing and this should be taken into consideration when evaluating a patient.

Family roles and communication styles may also differ based on culture. Certain cultures have strong family values or close-knit family structures. As a result, the healthcare encounter with patients from these cultures may involve the participation of other members of the family. Communication styles will also vary; thus, clinicians should be aware of communication characteristics when working with patients of various cultures. Table e3-4 includes various characteristics related to healthcare beliefs, practices, and values that have been found in various racial and ethnic groups represented among the population of the United States.

TABLE e3-4

Examples of Cultural Beliefs, Values, and Practices

Various Beliefs on Health and Illness	• Health may result from harmony with nature; illness results from disharmony • Illnesses may be due to natural causes (God's plan, eating the wrong food, environmental) or unnatural causes (evil origins such as demons, spirits, "hexes," or the "evil eye") • Health may involve the balance of yin (cold) and yang (hot) or wet and dry; illness often caused by an imbalance • The human body may be divided into two halves—a positive and a negative energy pole, and the energy of the body can be controlled by spiritual means • A person's body may be viewed as a gift and should be cared for and well maintained • Illness is due to destiny, fate, or *karma* • Illness is due to punishment for sins from a higher being • Preference for cure as opposed to prevention
Health Care Practices	• Time orientation may be focused on the "present" vs "future" and may impede preventive care and follow-up • Blood or organ donation may be rejected out of fear of hastening donor's death • May refer to certain foods as causing "high" or "low" blood, which may be confused with blood pressure or blood count • May use combination of Western medicine and traditional medicine • May be upset by the practice of drawing blood (source of life for the body that may not be regenerated) • Deep respect for the body may lead to refusal of painful procedures for diagnostic workups or surgery unless absolutely necessary • Cutting or shaving of hair should be discussed with patient as this practice may be associated with mourning in some cultures • Mental illness may be seen as a stigma and may prevent patients from seeking psychiatric care • Patient may wear items considered to be sacred (eg, threads, medallions, other religious items); permission to remove should be obtained when possible • Healthcare providers are often seen as authorities; patients may take a more passive role and prefer for a provider to make decisions
Complementary and	• May use traditional or faith healers (eg, priests, magicians, voodoo doctors, medicine men/women,

alternative medicine (CAM) use	*curanderos/curanderas*) and/or religious rituals (eg, prayers, ceremonies, visiting shrines, making promises to God(s) or saints) • Folk medicine/traditional medicine/CAM may include ◦ Acupuncture ◦ Candles lit as a form of prayer or invoking God ◦ Coining, pinching, or cupping of skin to draw out illnesses ◦ Copper or silver bracelets or amulets to protect the wearer ◦ Massage ◦ Moxibustion ◦ Poultices to draw out infections ◦ Sweat baths or sweat lodges ◦ Use of herbs ◦ Use of "hot" or "cold" foods (based on the qualities of the food and not on temperature) may be recommended for certain conditions
Role of Family	• Families may be matriarchal or patriarchal ◦ Women may defer to men for decision-making in patriarchal families whereas women in matriarchal families are primary decision-makers • High esteem/respect for elders found in many cultures • Community/family may be viewed as more important than the individual • Family members may accompany patients to healthcare encounters and may want to be included in decision making and integrated into the treatment plan for the patient • In some cultures, family members may not permit discussion of serious healthcare issues directly with the patient
Communication Styles	• Some patients prefer to be addressed as "Mr." or "Mrs." or by professional title • Hand-gestures (eg, pointing, beckoning with index finger) may be insulting in some cultures • Some patients may avoid direct eye contact as a sign of respect • Developing and maintaining personal relationships and trust toward their healthcare providers may be important for patients • Patients may prefer same-gender providers due to modesty

Data from References 14, 38, 51,71.

An additional aspect of culture is religion, which can influence health beliefs and practices across the lifespan. Patients and healthcare providers who align with a religion or spiritual path may adapt their lifestyle to integrate unique diet and fasting, and many may avoid animal-based medicinal agents. Among various religions and practices, patients and providers may recite prayers and/or seek support from a spiritual leader as ways to honor their faith tradition and beliefs. Differing beliefs regarding contraception and family planning also exist across western and eastern religions. In some world religions, any form of contraception is unlawful while other religions have differing beliefs on prevention (eg, condoms, birth control pills), interruption (eg, Plan B), and abortion.[51,72] Table e3-5 lists some health beliefs and practices found in common worldwide religions.

TABLE e3-5

Healthcare Practices and Beliefs Found in Selected World Religions[a]

	Medications or Special Dietary Restrictions	Healing Practices
Buddhism	Vegetarian diet Some holy days require fasting	Prayer Picture of Buddha may be used to facilitate meditation
Christian Catholic	May use medications May avoid meat on Fridays during Lent	Prayer, candles, laying on of hands Holy sacraments may be offered to the sick Visits from priest
Christian Protestant	Varied restrictions and permission	Prayer Diverse opinions of divine intervention Visits from pastor Some beliefs prevent blood transfusions or organ transplant
Hinduism	Vegetarian diet; meat products often prohibited Several holy days require fasting Most medications permitted	Includes traditional Faith healing
Islam	Pork and alcohol often prohibited (may include medications that are pork-derived or that include alcohol) Meat preparation meets *halal* (“lawful”) standards Fasting during Ramadan	Some herbal remedies and faith Visits from imam
Judaism	Pork and shellfish products often forbidden (may include medications or supplements that are pork- or shellfish-derived) Meat preparation meets Kosher standards Fasting during Yom Kippur (day of atonement)	Prayer Visits from rabbi

[a] These practices and beliefs may be found among persons (not all) who identify with the religions listed.

Data from References 51,72.

To illustrate some of these differences, consider the following examples.[51] A patient who comes from the Jewish or Muslim faith may be unwilling to accept omega-3 fatty acids as a therapy option for hypertriglyceridemia because the gelatin formulation may not adhere to the dietary restrictions of the religions. A female patient whose religion embraces greater physical distance between women and men in social situations may not be comfortable working with a male healthcare provider. A devout Christian family may be concerned about discussions of contraception or emergency contraception.

To better elicit information about a patient's religious or spiritual concerns, providers may ask the following during the patient encounter: ***"I feel that I can help you better if you can tell me what religious or spiritual needs I should consider in your healthcare."***

UNDERSTANDING AND WORKING WITH THE LGBTQIA+ COMMUNITY

To understand the disparities that affect members of the Lesbian, Gay, Bisexual, Transgender, Queer, Intersex, and Asexual (LGBTQIA+) populations, it is imperative to first master understanding of the unique identities that are encompassed under the LGBTQIA+ acronym umbrella. While a single acronym may suggest a cohesion of concepts and identities, the people that comprise the LGBTQIA+ communities are heterogeneous. The groups have a variety of beliefs, identities, and understandings, but all are bound by common experiences of stigma and discrimination.[73]

Furthermore, mastery of vocabulary related to how individuals within the LGBTQIA+ community identify is of utmost importance. Sexual orientation describes a person's sexual or emotional attraction to others, whereas gender identity is an intrinsic sense of being a woman, man, neither, or something else. For example, identifying as a lesbian, gay, or bisexual describes sexual orientation. Identifying as transgender refers to a person's gender identity; transgender people may be straight, gay, or bisexual. Gender expression is defined as the way a person communicates their gender to the world through mannerisms, clothing, speech, behavior, or in other ways, and these may or may not align with their gender identity or assigned sex at birth.[74] Table e3-6 includes a summary of definitions related to the LGBTQIA+ population.

TABLE e3-6

Select Definitions Related to the LGBTQIA+ Population

Term	Definition
Asexual (adjective)	"Describes a person who experiences little or no sexual attraction to others. Asexual people may still engage in sexual activity."
Bisexual (adjective)	"A sexual orientation that describes a person who is emotionally and physically attracted to women/females and men/males. Some people define bisexuality as attraction to all genders."
Cisgender (adjective)	"A person whose gender identity is consistent in a traditional sense with their sex assigned at birth; for example, a person assigned female sex at birth whose gender identity is woman/female."
Gay (adjective)	"A sexual orientation describing people who are primarily emotionally and physically attracted to people of the same sex and/or gender as themselves. Commonly used to describe men who are primarily attracted to men, but can also describe women attracted to women."
Gender binary structure (noun)	"The idea that there are only two genders (girl/woman and boy/man), and that a person must strictly fit into one category or the other."
Gender-diverse (adjective)	Gender-diverse describes people whose gender identity falls outside traditional ideas of male or female. Some gender-diverse people feel like a mix of more than one gender; some feel more like one gender some of the time, and a gender that is something else at other times. A gender-diverse person may feel like both genders sometimes, and sometimes no gender at all.
Gender Expression (noun)	"The way a person communicates their gender to the world through mannerisms, clothing, speech, behavior, etc. Gender expression varies depending on culture, context, and historical period."
Gender	"A person's inner sense of being a girl/woman/female, boy/man/male, something else, or having no gender"

Identity (noun)	
Intersex (adjective)	“Describes a group of congenital conditions in which the reproductive organs, genitals, and/or other sexual anatomy do not develop according to traditional expectations for females or males. Intersex can also be used as an identity term for someone with one of these conditions.”
Lesbian (adjective, noun)	“A sexual orientation that describes a woman who is primarily emotionally and physically attracted to other women.”
Nonbinary (adjective)	“Describes a person whose gender identity falls outside of the traditional gender binary structure of girl/woman and boy/man.”
Pansexual (adjective)	“A sexual orientation that describes a person who is emotionally and physically attracted to people of all gender identities, or whose attractions are not related to other people’s gender.”
Queer (adjective)	“An umbrella term describing people who think of their sexual orientation or gender identity as outside of societal norms. Some people view the term queer as more fluid and inclusive than traditional categories for sexual orientation and gender identity. Although queer was historically used as a slur, it has been reclaimed by many as a term of empowerment. Nonetheless, some still find the term offensive.”
Sexual Orientation (noun)	“How a person characterizes his/her emotional and sexual attraction to others.”
Transgender (adjective)	“Describes a person whose gender identity and sex assigned at birth do not correspond based on traditional expectations; for example, a person assigned female sex at birth who identifies as a man; or a person assigned male sex at birth who identifies as a woman. Transgender can also include people with gender identities outside the girl/woman and boy/man gender binary structure; for example, people who are gender fluid or non-binary. Sometimes abbreviated as trans.”

Data from Reference 74.

Social Determinants of Health and Health Disparities in the LGBTQIA+ Population

Members of the LGBTQIA+ population face unique challenges, many of which are shaped and propagated by an extensive history of oppression and discrimination. There are many complex social determinants of health that mold the experiences of members of the LGBTQIA+ community and transcend all ages, races and ethnicities, religions, identities, and social classes. These determinants of health stem from many places, including the legality of discrimination in access to health insurance, employment, housing, marriage, child adoption, and retirement benefits, the lack of anti-bullying laws, and a shortage of health care providers who are culturally competent and knowledgeable in LGBTQIA+-specific health matters.[75] Additionally, there is a lack of social programs aimed at addressing many of the issues faced by various subpopulations of the LGBTQIA+ community.[75]

The social determinants of health described above have led to many disparities within the LGBTQIA+ population, especially related to accessing, navigating, and thriving in the healthcare system. With regard to access, members of same-sex relationships are significantly less likely to have health insurance and report higher rates of unmet health needs.[73]

There are several examples of identified health disparities among members of the LGBTQIA+ population as well. For example, men who have sex with men (MSM) and transgender persons have a greater risk of HIV and other sexually transmitted infections, with even greater disparities demonstrated in LGBTQIA+ communities of color.[73,75] Rates of human papillomavirus–associated anal cancers in MSM are 17 times greater than heterosexual male counterparts.[73] LGBT populations have the highest rates of tobacco, alcohol, and other drug use.[75] Additionally, studies have suggested that gay, lesbian, and bisexual people have higher rates of depression, anxiety, and suicidal ideation, and LGBT youth are 2 to 3 times more likely to attempt suicide.[73,75] More specifically, members of the transgender community have a high prevalence of mental health issues, risk of suicide, and violence and victimization.[75]

While there are many players in the development and propagation of these social determinants of health, the creation of uniform guidance has created a unified approach to tackling many of these issues.

Strategies for Overcoming Barriers and Creating Inclusive Environments for LGBTQIA+ Patients

Discrimination toward LGBTQIA+ people is common in healthcare settings, and this can lead to fear of a negative experience or avoidance of the health system altogether. There are a few strategies that can be employed to ensure that LGBTQIA+ people receive the quality, inclusive, and affirming care that they deserve.

Creating and Revising Organizational Policies

The creation or revision of nondiscrimination policies to include gender identity, gender expression, and sexual orientation should be completed to protect LGBTQIA+ people in the workplace. Policies that allow transgender and gender-diverse people to use the bathroom that align with their gender identity should also be created if those do not already exist. Any created policies should be posted visibly and clearly in physical and virtual locations.[76]

Communication

Improving communication with LGBTQIA+ patients requires training at all levels of an organization and should encompass many areas relevant to the LGBTQIA+ population, including behavioral health, sexual and reproductive health, transgender and gender-diverse clinical care, and HIV prevention and treatment.[76]

Gender-assuming language such as, “Ms.,” “Mr.,” “Sir,” or “Ma’am,” should be avoided when a patient’s pronouns are not known. Referring to the patient by their name or saying, “The patient is in the waiting room,” avoids assuming gender and is more inclusive.[77] Table e3-7 includes a list of outdated and insensitive terms that should be avoided and provides recommended terms that are more appropriate and inclusive.

TABLE e3-7

Examples of Outdated Versus Recommended Terms When Working with Members of the LGBTQIA+ Communities

Outdated Term	Recommended Term
Biological female/male	Assigned female/male at birth
Hormone replacement therapy	Gender-affirming hormone therapy
Female-to-male (FTM) and Male-to-female (MTF)	Transgender man and transgender woman
Preferred name	Chosen name or name used
Preferred pronouns	Pronouns
Sex change, sex reassignment surgery, gender reconstruction surgery	Gender-affirming surgery
Sexual preference/lifestyle	Sexual orientation
Transgendered	Transgender

Data from Reference 74.

Respectful and inclusive communication is especially important when working with transgender and gender-diverse (TGD) people. Many TGD people may have a different chosen name from the name on their identification documents, and their pronouns may also be changed and/or unfamiliar.[77]

Recommended strategies regarding use of pronouns:

- If a person's pronouns are not clearly known or documented, it is important to clarify by asking, *"How would you like to be addressed?"* or *"What name do you go by and what are your pronouns?"*
- If a mistake is made and the wrong pronouns used, a succinct apology and correction can be effective in conveying honesty and openness to learning. *"I apologize. I am still learning. Let me try again,"* is an example of how to effectively correct a mistake.
- Finally, staff should be trained to understand and rectify any discrepancies that may occur as a result of different chosen names/pronouns from those in the medical record. Questions such as, *"Could your chart be under a different name?"* or, *"What is the name on your insurance?"* can be useful in handling clerical issues while sparing any embarrassment or disrespect to the patient.

Collection of Data

Many state and national surveys do not collect population-level data on sexual orientation and gender identity (SOGI), which is imperative to help inform effective health promotion strategies as well as produce nationally representative information about the LGBTQIA+ populations.[75,78]

Registration and electronic health records should have standardized SOGI demographic questions to monitor and improve the care process. Collection of patient pronouns can be useful to improve communication among medical staff.[76] Forms used should be evaluated for inclusivity related to relationship status, gender identity, and sexual orientation. For example, instead of "marital status," the use of "relationship status" is more appropriate when collecting demographic information.

Recruitment and Representation

Those responsible for hiring decisions, including those within healthcare organizations, should strive to hire a diverse workforce that represents the

LGBTQIA+ communities. Medical staff should be proficient in LGBTQIA+ health and/or demonstrate an interest in gaining the necessary knowledge and skills to provide inclusive care.[77]

CROSS-CULTURAL COMMUNICATION

⑦ Developing communication skills to interact with diverse populations includes recognizing personal styles of communication. However, providers should have communication skills to recognize if a barrier may exist, and they should work to care for patients regardless of the language they speak. Understanding personal communication styles provides insight to clinicians so they may be able to prevent or acknowledge any bias or expectations during clinical encounters. By recognizing personal cultural biases, clinicians can better serve the patients.

Barriers related to cross-cultural communication can affect the provider-patient relationship. From the perspective of the Joint Commission, the threat to effective communication is threefold: language differences, cultural differences, and low literacy levels.[47,79] Patients can also have communication barriers because of differences in age or gender with the provider.[8] A person with a lower level of education may not be comfortable working with a provider who has obtained a college education and/or attended graduate school. An older patient may not believe that a younger provider has enough work or life experience to be qualified. A man from a more conservative religious upbringing may not feel it is appropriate to be counseled by a female provider. Other barriers to care may exist because of fear and distrust in the provider due to race or ethnic background, prejudices, or lack of familiarity or knowledge of the culture.[8,53] For example, a patient who is of Chinese descent may not feel comfortable with a provider who is Mexican American because of a perception of unfamiliarity and a lack of opportunity to interact with persons of the other background.

Communication Skills

Communication skills needed to work with patients from diverse cultures include looking for nonverbal cues.[8,51,53] Providers can often gain clues for how to interact with patients by observing their behaviors and following patients' mannerisms. Patients will have varying preferences of eye contact, personal space, and physical contact.[8,51] Some patients prefer indirect eye contact and may view direct eye contact as rude or intrusive. A comfortable distance for personal space also varies across cultures.[8,53,80] In some cultures, patients prefer only a handshake or a nod of acknowledgment for greetings, whereas in other cultures, patients will welcome a light tap on the shoulder or even a hug.

Verbal cues include recognizing whether patients prefer to be called using their first name or last name.[8,14,51] Some patients embrace the opportunity to talk and get to know their provider before jumping into medical information. Using a vocabulary that is consistent with the culture and education of patients is another strategy that can help providers gain trust.

To develop skill sets to work with patients from diverse communities, providers can identify cultural "brokers" or community liaisons.[15] These liaisons are often respected community members and leaders who recognize the importance of connecting the healthcare community with the community being served. Liaisons may be religious leaders or mothers and grandmothers in the community. The key is to align providers with these community liaisons to help interpret what cues (nonverbal and verbal) and ways of communicating are most appropriate.

LEP and Hearing Impairment

According to Census data, nearly 22% of people living in the United States who are 5 years of age and older speak a language other than English in the home.[16] LEP occurs when a person is not able to communicate effectively (reading, speaking, writing, or understanding) in the English language because of English not being the primary language.[81,82]

⑧ Linguistic competency encompasses understanding issues related to working with patients with LEP and/or hearing impairments such as learning basic terms and greetings, working with an interpreter or language-assistance lines, and using non-English patient education/materials.

For healthcare providers to more effectively communicate information to patients with LEP, it is important to identify the most common languages spoken among their patients. As outlined in the CLAS standards, organizations receiving federal funds (indirect or direct) must provide meaningful access to persons with LEP.[44,81,82] Using professionally trained interpreters improve clinical care, improve patient safety, and increase satisfaction for patients with LEP.[83–86] In addition to having qualified interpreters, it is important to train healthcare providers to use and interface with professional phone interpreter services.[87] A variety of online resources are available to begin learning about working with interpreters and translators (Table e3-8).

TABLE e3-8

Resources for Working with Interpreters and Translators

Tips for Working with Healthcare Interpreters: https://refugeehealthta.org/access-to-care/language-access/best-practices-communicating-through-an-interpreter/
Tips for Working with Sign Language Interpreters: www.ncdhhs.gov/document/tips-working-sign-language-interpreters
Sight Translation and Written Translation: Guidelines for Healthcare Interpreters. The National Council on Interpreting in Health Care www.ncihc.org/assets/documents/publications/Translation_Guidelines_for_Interpreters_FINAL042709.pdf

While interpreter services may exist, challenges persist to identify patients with language assistance needs as well as to maintain a consistent and qualified language assistance workforce in the healthcare system.[88] If a trained interpreter is not available, the clinician may need to work with an ad hoc interpreter (eg, bilingual coworker, family member, and friend), which poses a greater risk for error.[53] Children (minors) should not be used as interpreters. Clinicians should be actively aware of the interpretation situation. If the interpretation is muddled or the process seems confusing, then it is appropriate to insist upon finding a more reliable source of interpretation.

Organizations and clinicians can also create a positive environment for patients with LEP by having written materials translated into the common languages found in the served population. Materials should be translated by certified translators and not by staff members, family, or friends who state that they are bilingual.

Tools for Working Across Cultures

Clinicians should recognize that assessing culture in the patient encounter is not necessarily a new concept.[53] The “social history” of patients provides room to explore the patient’s individual and family situation, work and home environment, unique dietary needs, and education background, among other sociocultural influences. ⑨ Fortunately, tools have been developed to help providers further address unique cultural situations that can arise in the patient encounter.

One model frequently cited for working with patients from diverse cultures is LEARN (listen, explain/empathize, acknowledge, recommend/respect, and negotiate).[80] In the LEARN model, providers are called to ***listen*** to their patients’ perceptions of their health with an open mind. Providers should then take time to ***explain*** their perceptions and ***empathize*** with the patient. ***Acknowledgment*** of commonalities and differences in the approach to understanding health and treatment options for the patient can help to build trust. When providers ***recommend*** a treatment plan in a way that is ***respectful*** of the patient’s culture and beliefs, the provider and patient can find a common ground. With this baseline respect, a plan can be ***negotiated*** to ***navigate*** through the healthcare system.

While barriers do exist for cross-cultural communication, clinicians can overcome these challenges by understanding verbal and nonverbal cues to communication. They also should recognize that quality interpretation is essential in the patient encounter. Tools for navigating across cultures include learning how to listen, empathize, and negotiate a treatment plan with patients.

ORGANIZATIONAL AND INDIVIDUAL SELF-ASSESSMENT

⑩ Both individuals and organizations demonstrate the capacity for providing a culturally competent environment. Before understanding other cultures, *individual practitioners* should understand their own personal values and beliefs. Additionally, assessment of attitudes, practices, policies and structures *within an organization* can assist in planning for and incorporating cultural competence into the provision of healthcare within organizations.[89,90]

The process of self-evaluation may begin with the simple act of a practitioner reflecting on the values and beliefs that shape their world view, their perceptions of health and illness, and the existence of stereotypes or myths about other cultures.[15] To assist in this process, self-assessment instruments have been developed to guide individual healthcare providers in their reflection of cultures, values, and beliefs.

A variety of assessment tools designed for use by individual practitioners are available in both written and online formats (Table e3-9 provides recommended websites that have links to various cultural competency assessments). Domains that are typically assessed by these instruments include values and belief systems, communication styles, experience in cultural diversity, materials and resource evaluations, and others. Many of these tools pose specific examples or questions within each domain that allow practitioners to assign ratings that reflect their level of cultural competence. Although there are no correct answers, these instruments provide individuals the opportunity to identify personal attitudes, values, and beliefs that do not foster cultural competence. By becoming aware of these issues, the practitioner may then make plans to improve upon or change these characteristics and move toward a more culturally competent approach to providing healthcare.

Data from References 89,90.

The assessment of the cultural competence of organizations and systems is just as important as individual assessments and should not be overlooked. Assessing the cultural competency of an organization promotes the principles of equal access and the provision of services in a nondiscriminatory manner.[2] To plan for and incorporate cultural competence into an organization, attitudes, policies, practices, and structure within the organization should be considered. An essential part of this assessment involves determining the needs, preferences, and satisfaction of patients and consumers who are served by the organization. Tools that may be used by organizations to assess cultural competence are also available from links included in the accompanying table (see Table e3-9). Additionally, steps for planning and implementing an organizational self-assessment are summarized in Table e3-10.

TABLE e3-10

Steps for Planning and Implementing Organizational Self-Assessment

1. Cultivate leadership among members of the organization to promote self-assessment.
2. Get "buy-in" from personnel, consumers, and communities.
3. Ensure community collaborations and partnerships.
4. Build support for the process by creating a committee, work group, or task force with responsibility for overseeing the self-assessment process.
5. Allocate personnel and fiscal resources.
6. Manage logistics.
7. Analyze and disseminate data.
8. Take the next step to establish organizational priorities and develop a strategic plan with goals and objectives.

Data from Reference 90.

Regardless of which tool is used, an assessment of cultural competency should be conducted periodically on an ongoing, long-term basis.[89]

Individuals and organizations are on a cultural-competency continuum at all times, with varying levels of awareness, knowledge, and skills. Periodic use of these tools can help individuals and organizations identify in which direction they are moving on the continuum in order to make necessary adjustments.[91]

Engaging in assessments of cultural competency can result in several benefits to the individual practitioner or organization.[89] One benefit includes the ability to determine whether providers or healthcare organizations are meeting the needs of the patients being served. Additionally, the process can improve patient and customer satisfaction, and allow for the identification of strengths that the individual practitioner or organization has to offer. Ultimately, conducting assessments allows for the recognition of opportunities for growth and improvement to create a healthcare environment that can achieve better patient outcomes.

CONCLUSION

A diverse society will yield diverse health beliefs and practices. The influence of culture on healthcare encompasses understanding social determinants of health and how environments and community networks help shape the health of individuals and families. The United States—with its culturally diverse society and health disparities, patient-safety concerns, and workforce shortages—has unique opportunities and challenges in patient care. To work in this environment, clinicians should understand legal and regulatory issues related to cultural and linguistic competency. To excel in diverse patient care, providers need the knowledge and skills to elicit patients' explanation of their health status, recognize potential cultural influences on healthcare beliefs and practices, and communicate effectively with patients from different languages and cultures. Individual and organizational self-assessments can reveal helpful information about attitudes, values, and capacity to provide culturally and linguistically responsive services to patients and communities. The ability for providers and organizations to navigate well in a diverse population can help to create a safer and more equitable healthcare environment for patients to receive care.

ABBREVIATIONS

CAM	complementary and alternative medicine
CLAS	culturally and linguistically appropriate services
HRSA	Health Resources and Services Administration
LEARN	listen, explain/empathize, acknowledge, recommend/respect, and negotiate
LEP	limited English proficiency
LGBT	lesbian, gay, bisexual, transgender
LGBTQIA+	lesbian, gay, bisexual, transgender, queer, intersex, asexual
MSM	men who have sex with men
PEM	patient explanatory model
SOGI	sexual orientation and gender identity
TJC	the joint commission
TGD	transgender and gender diverse
WBM	western biomedical model
WHO	World Health Organization

SELF-ASSESSMENT QUESTIONS

1. Which of the following is a compelling reason for healthcare providers to strive toward cultural competency and promoting diversity in healthcare?

   A. Health disparities are declining and are no longer relevant.

   B. The diversity of patients encountered in the United States has plateaued.

   C. Health professional shortages are no longer a concern.

D. Medication errors can be reduced by improving linguistic competency.

2. Social determinants of health are factors that affect the quality of life, functioning, and health of individuals. All of the following are examples of social determinants of health *except*?

A. Neighborhood and built environment

B. Genetic makeup

C. Economic stability

D. Access to high-quality education

3. Based on the cultural competency models addressed in this chapter, which of the following statements is *true*?

A. The LEARN model describes providers as going through distinct stages of change ranging from cultural destructiveness to cultural proficiency.

B. Cultural competency is achieved through experience, skills, knowledge, and a positive attitude.

C. The Purnell model describes providers as progressing through a continuum of cultural consciousness ranging from the unconsciously incompetent to the unconsciously competent.

D. Cultural humility plays a minor role in connecting the skills, encounters, and desire to work across cultures.

4. According to the 2000 Executive Order 13166 of Title VI of the Civil Rights Act, which of the following services should a healthcare organization meet to receive federal funding (eg, Medicare)?

A. Recruit, retain, and promote a diverse staff and leadership representative of the service area demographics

B. Offer and provide meaningful access to language services at a nominal cost to patients with limited English proficiency

C. Make easy-to-understand printed materials available in languages used frequently in the population served

D. Using family or minors as interpreters may be used if requested by the patient

5. The Patient Explanatory Model includes which of the following?

A. Explaining the pathophysiologic process of diseases

B. Identifying potential causes of illness

C. Involving the family and community in deciding the treatment for a patient

D. Navigating between spiritual and family leaders to help the patient improve

6. The "4 C's" is a simple method to elicit patients' understanding of their health and illnesses. Which of the following is an example of one of the questions that is asked of patients in this model?

A. "What do you think will cure your condition?"

B. "When did you complete your last course of medication therapy?"

C. "What will the problem cost you?"

D. "What concerns do you have about your health condition?"

7. When striving toward cultural competency, which of the following statements about stereotypes, generalizations, and patient care is *true*?

   A. Generalizations can help to provide a framework for understanding how patients may respond to a health-related situation.

   B. Stereotypes can help to form reasonable assumptions about how patients from different cultures will behave in the healthcare setting.

   C. Stereotypes and generalizations can be helpful in creating a positive healthcare environment.

   D. Stereotypes and generalizations are not useful in understanding how a patient may react in a healthcare setting.

8. Each of the following statements are true regarding diverse healthcare beliefs or practices that are found in various racial and ethnic groups in the United States *except*?

   A. Female patients from patriarchal families may defer to male family members for decision-making.

   B. Trust in the US healthcare system exists because of previous efforts for equality (eg, Tuskegee syphilis study)

   C. Patients may use traditional or faith healers to help them address health concerns

   D. Avoidance of direct eye contact may be seen as a sign of respect

9. Which of the following is considered an outdated and/or insensitive term?

   A. Preferred pronouns

   B. Sexual orientation

   C. Assigned male at birth

   D. Chosen name

10. Effective strategies for overcoming barriers and creating inclusive environments for LGBTQIA+ patients include which of the following?

    A. Creating or revising nondiscrimination policies for sexual orientation only

    B. Assigning transgender and gender-diverse patients to another provider when chosen names or pronouns are incorrectly used

    C. Avoiding use of gender-assuming language such as “Ms.” or “Mr.”

    D. Encouraging medical staff to be proficient in LGBTQIA+ care after caring for a member of the LGBTQIA+ community

11. Which of the following is an example of a social determinant of health that affects the LGBTQIA+ community?

    A. Legal discrimination in accessing health insurance, employment, housing, marriage, adoption, and retirement benefits

    B. Abundance of social programs targeted toward the LGBTQIA+ community

    C. Existence of extensive anti-bullying laws

    D. Surplus of culturally competent and knowledgeable healthcare providers

12. Examples of communication styles that work across cultures include:

    A. Shaking hands as a form of respect

    B. Providing ample distance to show respect of interpersonal space

    C. Using the first name to address a patient

    D. Observing patient behaviors and trying to follow them

13. Of the following choices, the most appropriate way to determine how to communicate with a patient from a different culture and language than your own is to:
    A. Provide as much information as possible to demonstrate professional competency
    B. Use a variety of written resources about the culture of the patient before the visit and use only this information to conclude your treatment approach
    C. Talk to the bilingual staff members and ask how they would want to be treated
    D. Treat the patient as they would want to be treated and use a trained interpreter
14. If you do not speak the same language as your patients, what would be the optimal way to conduct the patient visit?
    A. Use a family member to interpret
    B. Ask a bilingual staff person to interpret for you
    C. Use a trained interpreter
    D. All of the above
15. Assessment of organizational values and beliefs about diversity and culture are important for providing a positive and open environment for patient care and should be conducted:
    A. When an organization is expecting an accreditation or licensure survey.
    B. On an as-needed basis for performance improvement.
    C. If patient satisfaction surveys reveal poor outcomes.
    D. Periodically with long-term considerations for the organization.

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** Changes in demographics, the existence of health disparities, the need to promote patient safety, and persisting healthcare workforce shortages are among the reasons for needing cultural and linguistic competency skills and promoting diversity and equity in healthcare. Thus, Answer Choices A-C are incorrect. Answer Choice D is an example of how patient safety can be improved by striving toward cultural competency and promoting diversity in healthcare.

2. **B.** Social determinants of health include factors related to the places where people live, work, worship, or play as well as the structural environments within which they live (see Fig. e3-1). They include neighborhood and built environments (Answer Choice A), economic stability (Answer Choice C), education access and quality (Answer Choice D), as well as healthcare access and quality, and social and community context. A person's genetic makeup is largely non-modifiable and is not considered a social determinant of health; thus, Answer Choice B is correct.

3. **C.** Answer Choice C most accurately represents the correct description of one of the cultural competency models described (see Cultural Competency Models section of Chapter e3). The LEARN model is not a cultural competency model, rather it is a tool to foster cross-cultural communication between providers and patients (Answer Choice A is not correct). The models described in this chapter highlight that cultural competency is something that is not achieved; rather, it is a process that one can engage in and work toward (Answer Choice B is not correct). Cultural humility is an important part of developing cultural competency skills to work across cultures (Answer Choice D is not correct).

4. **C.** Executive Order 13166 of Title VI (2000) stipulates that federal agencies are required to evaluate and develop services for persons with limited English proficiency (LEP) and provide meaningful access to these services. Thus, Answer Choice C is correct in that it is one example of how services are made available to persons with LEP (see Standard 8 in Table e3-2). Although similar, Answer Choice B is incorrect since services for persons with LEP are not to be provided at an additional cost to the patient (see Standard 5 in Table e3-2). The other incorrect answer choices (A, D) are not

mandated by this Executive Order. Refer to the Limited English Proficiency and Hearing Impairment section of this chapter to read more on the use of family members as interpreters in the absence of trained, professional interpreter.

5. **B.** The Patient Explanatory Model (PEM) is a model that can be used to evaluate a patient's explanation of their disease (see Table e3-3). Thus, it can help the patient identify what they think are the potential causes of their illness (Answer Choice B is correct). The Western Biomedical Model is one that is used to explain the pathophysiologic process of disease (Answer Choice A is not correct). Answer Choices C and D are tools that can be used in providing cross-cultural care, but they are not specific components of the Patient Explanatory Model.

6. **D.** A modification of the Patient Explanatory Model is the "4 C's" (Call, Cause, Coping, Concerns), and this mnemonic device may be useful for providers. Providers may ask the patient: (1) "What do you **call** the illness?"; (2) "What do you think **caused** the disease or illness?"; (3) "How do you **cope** with the disease or illness?"; and (4) "What **concerns** do you have about your disease or illness?" Answer Choices A, B, and C are not elements of the 4 C's.

7. **A.** While generalizations may be helpful in providing a framework for how patients may respond based on their cultural background, stereotypes should be avoided since they can be damaging to patients as they are assumptions about how someone will behave (Answer Choices B, C, and D are incorrect). This is discussed further in the Cultural Values and Beliefs section of this chapter.

8. **B.** A variety of health beliefs and practices are observed from people across racial and ethnic groups (see Tables e3-4 and e3-5). Choices A, C and D are examples of health beliefs or practices that may be encountered among the population of the United States. Unfortunately, a lack of trust in the healthcare system does exist for some members of minority groups due to previous injustices such as the Tuskegee syphilis study (Answer Choice B is correct).

9. **A.** There are many previously used terms that are now outdated and/or insensitive. Answer Choice A is correct because the term "preferred pronouns" implies that using a person's pronouns is optional. The same concept applies to Answer Choice D, as "chosen name" should be used instead of "preferred name." Answer Choices B and C are incorrect because "sexual orientation" is preferred over "sexual preference/lifestyle" and "assigned male at birth" replaced the outdated term "biological male". Refer to Table e3-7 for more information.

10. **C.** Many times, a patient's pronouns may not be known and the use of gender-assuming language does not create an inclusive environment. Referring to the patient by their name or as "the patient" avoids any assumptions. Answer Choice A is incorrect because non-discrimination policies should include gender identity, gender expression, as well as sexual orientation. If a mistake regarding a patient's chosen name or pronouns is made, a succinct apology and correction would be an appropriate response, making Answer Choice B incorrect. Answer Choice D is incorrect because all members of the medical staff should be proficient in LGBTQIA+ health regardless of previous experiences in caring for a member of the LGBTQIA+ community.

11. **A.** Answer Choice A is correct because legal discrimination against the LGBTQIA+ community is prevalent in various aspects of insurance, employment, and social programs. There are limited social programs targeted toward the LGBTQIA+ community, a lack of anti-bullying laws, and a shortage of culturally competent and knowledgeable healthcare providers, making Answer Choices B, C, and D incorrect.

12. **D.** Communication preferences vary widely across cultures. The examples provided in Answer Choices A, B, and C may be acceptable for some members of cultural groups but not others. Providers can gain clues for how to interact with patients by observing their behaviors and trying to follow their mannerisms (thus Answer Choice D is correct).

13. **D.** Although exploring information about various cultures can serve as a guide when working with patients from different backgrounds, care should be individualized. Clinicians can apply the mantra "treat others as they would want to be treated" (also known as the Platinum Rule as discussed in the Cultural Values and Beliefs section of Chapter e3). Thus, Answer Choice D is the best answer to this question.

14. **C.** It is preferred that professionally trained interpreters be used to communicate with patients who speak a different language (Answer Choice C is correct). Healthcare providers should train to use and interface with professional interpreter services. When a trained interpreter is not available, clinicians may need to work with an ad hoc interpreter (eg, a family member, another staff member who is bilingual). However, this does pose a risk for error. It is important to note that children (minors) should not be used as interpreters. For more information, refer to the Limited English Proficiency and Hearing Impairment section of Chapter e3.

15. **D.** Organizational assessments of cultural competency should be conducted periodically on an on-going, long-term basis (Answer Choice D is

correct). Answer Choices A, B, and C list opportunities for organizations to schedule self-assessment activities, but they should not be the only times that organizations engage in these self-assessments. Various assessment tools are available to assist both individuals and organizations (see Table e3-9).

Chapter e4: Medication Safety

Robert J. Weber

KEY CONCEPTS

KEY CONCEPTS

① Medication errors (MEs) are defined as any mistake at any stage of the medication-use process; adverse drug events (ADEs) are MEs that result in injury.

② All MEs are preventable, while ADEs can be categorized as preventable and potential.

③ MEs occur at an alarmingly high rate, with some ADEs having fatal outcomes for patients.

④ MEs can occur at any step of the medication-use process: selection and procurement, storage, ordering and transcribing, preparing and dispensing, administration, or monitoring.

⑤ Determining the actual and potential root causes of MEs helps to correct future errors in the medication-use system.

⑥ Quality improvement methods that prevent MEs and thereby minimize ADEs include identifying the ME and/or ADE, understanding the reasons for the ME and/or ADE, designing and implementing changes to prevent an ADE or ME, and checking the outcome of that change.

⑦ Healthcare organizations have implemented various measures to reduce the incidence of MEs and ADEs, such as computerized physician order entry (CPOE), automated drug distribution systems, bar-code scanning, and "smart" infusion pumps with decision support and where information is passed in a bidirectional manner between the pump and the patient's electronic medical record (EMR).

⑧ Medication reconciliation or comparing a patient's current medication orders to all of the medications that the patient had been taking before any care transition (hospital admission, transfer, or discharge) is a vital process in preventing MEs and ADEs.

⑨ Promoting a "just culture" of medication safety cultivates trust in the workplace that makes personnel feel comfortable sharing safety information (eg, unsafe situations) and assuming personal responsibility and accountability for complying with safe medication practices.

BEYOND THE BOOK

BEYOND THE BOOK

1. Watch the https://tinyurl.com/tqh8n3k video entitled "CUSP: Understand Just Culture," sponsored by the Agency for Healthcare Research and Quality. This 5.5-minute video describes the fundamental tenets of a "just culture" environment with examples that clarify the concept.
2. Use the above video to think about a patient care situation where a medication error occurred—and how it was managed and resolved. Write down two to four ways the "just culture" concepts were used—or not used—in that situation.

INTRODUCTION

Medical errors are not a new phenomenon. Medical errors causing harm may lead to devastating effects on patients. In 1991, the Harvard Medical Practice Study showed that a significant number of people are victims of medical errors, and a subset experienced MEs. This landmark study reviewed the incidence of adverse events and negligence in hospitalized patients in the state of New York showing that almost 4% of patients experienced an iatrogenic injury (one caused by healthcare practices or procedures), prolonging their hospital stays.[1] Importantly, nearly 14% of those mistakes were fatal. Examples of mistakes noted in the Harvard study included renal failure from angiographic dye and a missed diagnosis of colon cancer. Drug complications were the most common type of outcome attributed to negligence, accounting for 19% of these preventable adverse events.[1]

The goal of medication therapy is achieving defined therapeutic goals to improve a patient's quality of life while minimizing harm.[2] Known and unknown risks are associated with the therapeutic use of prescription and nonprescription drugs and drug administration devices.[3] Mishaps related to medication therapy include both ADEs and MEs.[4]

MEs negatively affect patients' confidence in the healthcare system and increase healthcare costs. Research conducted by the American Society of Health-System Pharmacists (ASHP) showed that 61% of patients surveyed reported that they were "very concerned" about being given the wrong medicine during a hospital stay.[5] MEs are also very costly—to healthcare systems, patients and their families, and healthcare workers. The emotional cost of an ME is also significant, including the burden on the family for grieving loss or stress for the healthcare worker (often referred to as the "second victim") involved in an ME that caused harm.

Many MEs are not detected by standard reporting systems and often do not cause patient harm. According to the "Fourth Annual Report on Medication Errors in US Hospitals" by the United States Pharmacopeia (USP), 49% of MEs never reach the patient.[6] Many MEs have little to no clinical importance or have minimal impact on patient care. According to the 2002 USP study of the anonymous Web-based reporting system MEDMARx, 98% of reported MEs (n = ~190,000) resulted in no harm to the patient. Tragically, however, MEs do sometimes result in serious patient morbidity and mortality.[7] In fact, preliminary data from the Centers for Disease Control and Prevention (CDC) list accidents (of which MEs are included) as the fifth leading cause of death in the United States in 2010.[8]

The 1999 report "To Err Is Human" by the Institute of Medicine (IOM), a preeminent source, irrevocably changed the way MEs were viewed in health systems. In many ways, this was the first comprehensive report that quantified the problem of medical errors in health systems. The report stated that medical mistakes kill 44,000 to 98,000 patients annually in the United States, causing more deaths than breast cancer, motor vehicle accidents, and infections of human immunodeficiency virus.[9] In the years since this landmark publication, medication safety has become a priority across the country. Another IOM report in 2007, "Preventing Medication Errors," described system changes that are necessary to improve safety to include computerized physician order entry (CPOE), barcode-assisted medication administration (BCMA), multidisciplinary communication, and the active involvement of patients in their treatment.[10]

As mentioned previously, medication safety has attracted the attention of government and regulatory agencies, including The Joint Commission (TJC) and the Centers for Medicare & Medicaid Services (CMS). Both of these organizations have revised their standards to emphasize a systematic approach to identifying and preventing MEs and ADEs. Healthcare professionals are obligated to ensure that medications are used safely and errors are prevented. Web addresses for those and other organizations and government agencies involved in medication safety are listed in **Table e4-1**.

This chapter provides the healthcare professional with fundamental background information on the principles and practices of medication safety and reviews definitions, prevalence, causes, and methods for preventing MEs and ADEs. As more is known about identifying and preventing MEs and ADEs, the healthcare system will become a safer environment.

DEFINING MEDICATION ERRORS AND ADVERSE DRUG EVENTS

① Health professionals should use a standard definition of MEs and ADEs to foster a shared vision to reducing their prevalence. Doing so helps to ensure MEs and ADEs are viewed similarly among various disciplines and regions. It also helps to ensure continuity in their reporting based on published guidelines.

The IOM defines an ADE as an injury resulting from medical intervention related to a drug, which can be attributable to preventable and non-preventable causes.[11] The National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) defines an ME as follows: "Any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the healthcare professional, patient, or consumer."[11] This NCCMERP definition of MEs has recently been implemented in other agencies guidelines most notably CMS and TJC.[12,13]

Patients can experience an ADE even if the correct medication was prescribed and administered because an ADE refers to the effect the drug had on the patient, not necessarily that an error occurred in the medication process. This is in direct contrast to MEs, which involve any mistake in the medication process, regardless of patient outcome. Not all MEs lead to serious consequences; however, preventing MEs at any point in the medication-use process has the potential to reduce harm (eg, ADEs). Although an ME in one patient may not cause harm, that same ME in another patient could prove to be fatal.

It is important to understand the difference between MEs and ADEs. Broadly speaking, MEs describe process errors and ADEs describe MEs causing negative clinical outcomes. The following example illustrates the differences between MEs and ADEs. Consider the case of two patients (patient A and patient B) who each received a dose of digoxin that was too high for their respective compromised renal function. An ME in prescribing occurred in patient A and patient B because the incorrect dose was prescribed for each patient. However, harm from this prescribing error (digoxin toxicity) occurred only in patient A. This event would be documented as an ME and ADE in patient A and an ME in patient B.

② Put another way, all ADEs cause patient harm, but are not necessarily preventable. All MEs are preventable, but do not necessarily cause patient harm. ADEs can be categorized as preventable, non-preventable, or, if they have not actually occurred, potential.

MEs can be categorized by the node of the medication-use process in which the error occurred. For the purpose of safe medication management, TJC divides the medication-use process into the six critical processes shown in Fig. e4-1. Although MEs can occur at any stage in the medication-use process, upward of 80% of errors reported are in either the ordering and transcribing or administration processes.[14]

Another common method to categorize MEs is the NCCMERP Index for Categorizing Medication Errors Algorithm shown in Fig. e4-2. This algorithm categorizes MEs according to the severity of the outcome.[15] The algorithm provides the user an easy method to categorize an ME that occurred. To fully understand and use this algorithm, it is necessary to understand the following terms:

1. Harm: impairment of the physical, emotional, or psychological function or structure of the body and/or pain resulting therefrom
2. Monitoring: to observe or record relevant physiologic or psychological signs
3. Intervention: changes in therapy, active medical and/or surgical treatments, or other responses of health professionals or the patient
4. Intervention Necessary to Sustain Life: cardiovascular and respiratory support or other measures that maintain basic physiologic functioning

NCC MERP Index for Categorizing Medication Errors Algorithm

Harm
Impairment of the physical, emotional, or psychological function or structure of the body and/or pain resulting therefrom.

Monitoring
To observe or record relevant physiological or psychological signs.

Intervention
May include change in therapy or active medical/surgical treatment.

Intervention Necessary to Sustain Life
Includes cardiovascular and respiratory support (eg, CPR, defibrillation, intubation).

*An error of omission *does* reach the patient.

By and large, the classification system developed by NCCMERP has gained widespread acceptance (**Fig. e4-3**). This system allows for comparison of numbers and types of MEs across health systems. It takes into account whether or not the patient received the medication, what if any treatment or monitoring was required, and lastly, the outcome. Note that the same ME could occur in two patients, but if they had different outcomes, the error categories would be different. For example, if patient A received a 10-fold overdose of an opioid-containing medication and required naloxone to treat respiratory depression, this would be a category E error. However, if patient B received the same inappropriate dose of the same opioid-containing medication and was also treated with naloxone, but in this case the patient had to stay an extra night in the hospital, this would be a category F error. The NCCMERP Index for Categorizing Medication Errors, shown in Fig. e4-3, is a more concise diagram consisting of all the different categories.

FIGURE e4-3

It should be noted other approaches to categorization are sometimes used. One method is to simply judge whether or not MEs were clinically significant.[15] In addition, Hartwig, Denger, and Schneider developed a more elaborate, severity-indexed classification program.[16,17]

PREVALENCE

③ Each year in the US hospitals, 6.7% of all patients admitted will experience a medical error. Of these errors, 3.1% will cause harm, and 13% will have fatal outcomes. Surprisingly, a large percentage of medical errors occur frequently, and are both predictable and preventable. MEs and ADEs are both included in the broad category of medical errors. Preventable ADEs occur in 2% of hospitalized patients, and MEs resulting in harm contribute to approximately 7,000 deaths annually in the United States.[11]

Beyond their human toll, MEs and ADEs are economically costly as well. These errors can prolong treatment courses and hospital stays as well as require therapeutic and pharmacologic intervention. The IOM report noted that the hospital cost of an ADE averaged $4,700.[11] Putting this figure in perspective is important for understanding the costs associated with ADEs. Using published data to extrapolate the incidence of ADEs in a given hospital (6.7% of hospital admissions), an organization with 15,000 admissions per year (~40/day) could expect approximately 1,100 ADEs yearly at a cost of $5.2 million annually. Most strikingly, cost projections compiled in 2000 at the University of Arizona showed that the morbidity and mortality costs for MEs were in the range of $177 billion among the US ambulatory population alone.[17,18] The types of mistakes examined in that analysis include incorrect medications, wrong-site surgeries, hospital- or treatment-acquired infections, and mistaken identities.

With the involvement of the IOM and significant impact of MEs, accrediting bodies have added detailed error prevention standards. TJC, a standard-setting organization for hospitals and other healthcare organizations, implemented yearly goals for patient safety that weigh significantly in the organization's accreditation review of a hospital.[18] CMS requires certain conditions of participation for healthcare institutions to receive federal funding for Medicare patients. An example includes prevention of hospital-acquired complications during or after procedures such as surgery and catheterization. This requirement is heavily weighed during reviews in an effort to ensure that hospitals have adequate processes and practices in place to prevent medical errors.[19]

PRIMUM NON NOCERE

From the Oath of Hippocrates, this means “First, Do No Harm” and reiterates the role of healthcare workers in preventing ADEs. Most MEs do not result in patient harm. If harm occurs, it can range from an extra day of monitoring in the hospital to permanent bodily damage or even death.

MEs that are most likely to cause harm to the patient include incorrect administration of medication (such as inappropriately crushing tablets), delivering drugs through the wrong route (such as IV vs intramuscular), and dispensing wrong medications. Insulin, morphine, and heparin are cited as being the agents most frequently involved in errors that result in harm to patients.[20,21]

Causes of Medication Errors

④ As shown in Fig. e4-1, medication selection and procurement is the first step in the medication process. MEs in this step include failing to order adequate stock of a medication to meet patient needs, ordering expired or adulterated medication, confusion with substitutions during product shortages and recalls, and ordering the incorrect product, strength, or dilution.

The second step is storage. An ME occurs when any medication that has been stored improperly is subsequently given to a patient. This could include failing to refrigerate a medication or failing to protect a medication from light.

The third step is ordering and transcribing. MEs in ordering occur when the drug selected and/or its dose, frequency, or dosing duration is not appropriate for the patient’s disease or physiologic condition. MEs in the transcribing phase include failure to correctly interpret the medication order.

During preparing and dispensing, health professionals must obtain and package the correct drug, dose, or dilution of a product. Medication dispensing errors are defined as any discrepancy between the medication dispensed and the original prescriber’s order.

Likewise, an ME in administration is any discrepancy between how the medication is given to the patient and the administration directions from the physician or hospital guidelines.

MEs involved in monitoring and evaluating the effects of medication are defined as not ensuring proper follow-up of the therapeutic effect of a medication or failing to recognize an adverse effect of a medication.

One analysis showed that the most common errors involved prescriptions in which a medication was incorrectly prescribed (18.5%), dosage or quantity was incorrectly interpreted during dispensing (25.5%), and omission (25.6%), in which the prescribed medication was not administered.[21] Other studies have slightly different descriptions of the medication ordering process. 49% of MEs occur during the ordering phase, 11% during the transcribing phase, 14% during the processing (preparing and dispensing) phase, and 26% in the administration phase.[22] A majority of errors in the ordering phase are wrong dose or frequency, known drug allergy, and drug-drug interactions.[23] Many errors occur in the administration phase, such as wrong dose or incorrect drug administration technique.[23]

MEs are preventable. ADEs are preventable if they result from an error. In one analysis, two-thirds of ADEs are preventable with an incidence of error caused by provider negligence at around 40%.[24] This same study categorizes errors as diagnostic, treatment, preventive, or other. The key is in finding the appropriate system or process at the correct step in medication distribution in an attempt to completely alleviate the risk of error.

MEs occur for a number of reasons, including the following:

1. Ambiguous strength designation on labels or in packaging
2. Drug product nomenclature (look-alike or sound-alike names, use of lettered or numbered prefixes and suffixes in drug names)
3. Equipment failure or malfunction
4. Improper use of electronic order entry systems
5. Inaccurate dosage calculation

6. Inadequately trained personnel
7. Inappropriate abbreviations used in prescribing
8. Labeling errors
9. Excessive workload
10. Lapses in individual performance
11. Medication unavailable

Preventing Medication Errors

It is important to understand that it is human nature to make mistakes. Furthermore, medication-use systems are extremely complex. Therefore, it is vital to create systems with built-in safeguards in order to reduce risk and promote safe use of medications. Systems for ordering, dispensing, and administering medications should be designed to minimize or prevent error.

⑤ Errors can occur at any step in the medication-use process. For each type of error, it is important to determine the root cause, or main reason, for the error. After researching the error and determining its root cause, a tracking system for MEs should be created. Multiple examples of tracking systems are available; errors may be grouped by the type of error or the extent of patient harm.

⑥ To design safer medication delivery systems, data must be collected, analyzed, and trended. MEs can be classified by the type of technical error that occurred. The ASHP Guidelines on Preventing Medication Errors in Hospitals classifies errors as shown in **Table e4-2**. System failures teach health professionals a tremendous amount about the weaknesses inherent in today's complex medical delivery processes. Once tracking systems are in place for MEs and ADEs, processes and systems can be put in place to prevent errors. This may require an upgrade to the current computer program, an upgrade to that software, or an entirely new system. It may mean separating look-alike, sound-alike medications. It may mean creating preprinted orders based on guidelines to prevent inappropriate drug, dose, or monitoring. Training of staff may be required, and monitoring and follow-up are often needed.

TABLE e4-2

Types of Medication Errors

Type of Error[a]	Examples
Prescribing error	Incorrect drug selection (based on indications, contraindications, known allergies, existing drug therapy, or other factors), dose, dosage form, quantity, route, concentration, rate of administration, or instructions for use of a drug product ordered or authorized by physician (or other legitimate prescriber); illegible prescriptions or medication orders that lead to errors that reach the patient
Omission error[b]	Failure to administer an ordered dose to a patient before the next scheduled dose
Wrong time error	Administration of medication outside a predefined time interval from its scheduled administration time (this interval should be established by each individual healthcare facility)
Unauthorized drug error[c]	Administration of medication not authorized by a legitimate prescriber for the patient
Improper dose error[d]	Administration of a dose that is greater than or less than the amount ordered by the prescriber or administration of duplicate doses to the patient (ie, one or more dosage units in addition to those that were ordered)
Wrong dosage-form error[e]	Administration of a drug product in a different dosage form than ordered by the prescriber
Wrong drug-preparation error[f]	Drug product incorrectly formulated or manipulated before administration
Wrong administration-technique error[g]	Inappropriate procedure or improper technique in the administration of a drug
Deteriorated drug error[h]	Administration of a drug that has expired or for which the physical or chemical dosage-form integrity has been compromised
Monitoring error	Failure to review a prescribed regimen for appropriateness and detection of problems, or failure to use appropriate clinical or laboratory data for adequate assessment of patient response to prescribed therapy
Adherence error	Inappropriate patient behavior regarding adherence to a prescribed medication regimen
Other ME	Any ME that does not fall into one of above redefined categories

[a] The categories may not be mutually exclusive because of the multidisciplinary and multifactorial nature of MEs.

[b] Assumes no prescribing error. Excluded would be (1) a patient's refusal to take the medication or (2) a decision not to administer the dose because of recognized contraindications. If an explanation for the omission is apparent (eg, patient was away from nursing unit for tests or medication was not available) that reason should be documented in the appropriate records.

[c] This would include, for example, a wrong drug, a dose given to the wrong patient, unordered drugs, and doses given outside a stated set of clinical guidelines or protocols.

[d] Excluded would be (1) allowable deviations based on preset ranges established by individual healthcare organizations in consideration of measuring devices routinely provided to those who administer drugs to patients (eg, not administering a dose based on a patient's measured temperature or blood glucose level) or other factors such as conversion of doses expressed in the apothecary system to the metric system and (2) topical dosage forms for which medication orders are not expressed quantitatively.

[e] Excluded would be accepted protocols (established by the pharmacy and therapeutics committee or its equivalent) that authorize pharmacists to dispense alternate dosage forms for patients with special needs (eg, liquid formulations for patients with nasogastric tubes or those who have difficulty swallowing), as allowed by state regulations.

[f] This would include, for example, incorrect dilution or reconstitution, mixing drugs that are physically or chemically incompatible, and inadequate product packaging.

[g] This would include doses administered (1) via the wrong route (different from the route prescribed), (2) via the correct route but at the wrong site (eg, left eye instead of right), and (3) at the wrong rate of administration.

[h] This would include, for example, administration of expired drugs and improperly stored drugs.

Data from Reference 4.

⑦ Implementation strategies to reduce MEs:

1. Computerized provider order entry (CPOE)
2. Automated drug-distribution cabinets enabled with bar-code scanning
3. Robotic drug dispensing systems (intravenous and oral products)
4. Barcode-assisted medication administration (BCMA)
5. Smart IV infusion pumps with a two-way interface to an electronic medical record (EMR)

Studies have shown many MEs and ADEs are preventable. Numerous studies have shown roughly 25% of all MEs and ADEs would never have occurred if various strategies had been implemented. CPOE reduces preventable ADEs by 17% and decreases nonintercepted serious MEs by 50%.[25]

Other strategies, such as automated drug-distribution cabinets enabled with bar-code scanning, help to decrease storage and dispensing errors. This strategy, however, is not without its own potential for error as pharmacy technicians and others, such as nurses and pharmacists, must use the bar-code scanner when filling the cabinets and removing medications to assure for the safety double check.

The use of BCMA is growing in popularity with many health systems already implementing this technology. When used appropriately, BCMA can decrease MEs by 65% to 86%.[26,27] BCMA prevents medication administration errors in outpatient areas—most notably the emergency department where BCMA is not routinely used.[28] The BCMA process involves using medications dispensed by the pharmacy with a barcode on the medication. This barcode is on all medications regardless of route including IV medications. If the incorrect medication is scanned, a warning will appear. As with other strategies, there is potential for error with bar-code administration as well. Examples would include nurses who override the warnings or who administer the medication before scanning the barcode. Both of these instances could lead to either an ME or ADE or both.

Most IV products are delivered to patients using "smart pumps." These pumps allow the organization to program the pump with standard concentrations and standard infusion ranges, preventing the nurse from administering it outside specified limits for each drug. These pumps are also set up with soft and hard stops whereby if a nurse sets the pump outside specified ranges, the pump could alarm with a soft stop in which case the nurse could override it, or a hard stop in which case the nurse would be unable to override the alarm. The Institute for Safe Medication Practices cautions that while this technology can reduce MEs and ADEs, "smart pumps aren't smart by themselves." The information on most smart pumps cannot be viewed on the EMR as pump software is not owned by most EMR vendors. The next step to "close the loop" in preventing intravenous infusion errors is to integrate smart pumps with the EMR so that data are sent bidirectionally between the two technologies.

A new approach to preventing MEs is to use computer simulation technology to educate and train healthcare workers in preventing errors. Organizations have been using simulation to establish competency in a variety of areas, such as airway management, surgical procedures, and basic life support. A recent review of the literature noted a growing interest in establishing programs that simulate potential for MEs.[29] When properly designed, simulations may assist providers in preventing serious and fatal MEs by providing "real life" experience.

It is important to remember the significance of MEs and ADEs on patients and the healthcare system. The cost of improving systems and training is negligible compared with the value of lives saved. In addition, the introduction of technology brings on new errors; the hope is that these errors will cause less harm than historical dispensing errors. Healthcare workers must always be diligent in predicting new sources of error from any robotic or automated system.

MEDICATION RECONCILIATION

⑧ Medication reconciliation is one of the most important safety practices to reduce MEs during care transitions. It involves comparing and reconciling hospital admission and discharge medication orders with patients' home medications, or comparing medications when patients are moved among different areas in a hospital (eg, from intensive care unit to a regular care unit). Many health systems are using the emergency department as the point to perform admission medication reconciliation since 30% to 40% of those patients are being admitted. This task can be performed by the pharmacist, pharmacy intern, or pharmacy technician depending on state rules and regulations.

Inadequate reconciliation accounts for 46% of all MEs and up to 20% of all ADEs among hospitalized patients.[30,31] Furthermore, MEs can be reduced by more than 76% when medication reconciliation is implemented at hospital admission, transfer between units in the hospital, and hospital discharge.[32]

Medication reconciliation involves the following steps: determining a current list of medications; developing a listing of medications to be prescribed; comparing the two lists; making clinical decisions based on the two lists, as well as finalizing and communicating the list of medications to the patient and other clinicians. Medication reconciliation at discharge is extremely important to not only ensure patients know how they should take their medications and any side effects that may occur, but alert them to any new additions or deletions to their medication list.

"JUST CULTURE" OF PATIENT SAFETY

⑨ An accepted idea in patient safety is the "just culture" concept. Introduced by the attorney David Marx in 2001, it focused on the sequence of events that led to the error, rather than the person who made the error.[32] This concept encourages internal risk transparency, coaching and counseling of employees, avoiding negative retribution for errors, and gathering and then using information to prevent recurrence of the error.

Before "just culture," there were two main philosophies regarding errors in healthcare. These were the *punitive culture* and the *blame-free culture*. In the punitive culture, those who made an error were held personally responsible, regardless of the root cause. This was thought to discourage reporting of errors. The blame-free culture encouraged reporting of errors as there was no risk of punishment, regardless of the cause of the error. However, the lack of blame did not provide incentive against risky or even reckless behaviors.

The key distinguishing characteristic of "just culture" is that the focus is on the cause of the error, and therefore errors caused by system failures are not punished. However, reckless or negligent behaviors that lead to errors are punished. Therefore "just culture" has an inherent accountability not seen in a pure blame-free culture.

"Just culture" does not negate previous information provided in researching MEs. The "just culture" approach to MEs improves internal communication and reporting processes, resulting in an effective, successful error-reporting process.

The introduction of "just culture" of patient safety has afforded a great opportunity to prevent MEs and ADEs. Employees are encouraged to help design systems to reduce human error and risky behaviors. It is a proactive approach in which risks are reviewed and outcomes of events are evaluated. The approach allows the staff to be a stakeholder in the process of risk reduction, encouraging health workers to discuss and review errors without fear of retribution. A 2009 publication by TJC describes "just culture" as "an environment where employees hunger for knowledge and eagerly seek to understand risk."[31] The main focus in "just culture" is on systems and improving system designs.

CONCLUSION

MEs are a public health problem. They affect a large number of patients with the risk of causing severe patient harm. Errors can occur at any step in the medication-use process, from ordering to post-administration and monitoring.

Within a facility or health system, a set of clear definitions and guidelines of MEs and ADEs is needed. Once these definitions are set, a tracking process can be designed. The "just culture" approach encourages all employees to be stakeholders in the prevention of MEs and ADEs. The staff can design, follow, and review results of their own ME tracking process, all with this old adage in mind: "An ounce of prevention is worth a pound of cure."

Chapter e5: Medication Adherence

Fang-Ju Lin; Yen-Ming Huang; Yunn-Fang Ho

KEY CONCEPTS

KEY CONCEPTS

① Medication adherence is defined as the degree to which an individual takes medications recommended by healthcare providers in terms of the dose, route, frequency, and length of time.

② Better medication adherence is associated with optimal health outcomes.

③ Approaches to assessing medication adherence are classified as direct and indirect methods with various inherent limitations.

④ Direct methods of assessing medication adherence include bioassays or biomarkers to measure levels of drugs or their metabolites in body fluids.

⑤ Indirect methods of assessing medication adherence include self-report surveys, pharmacy refill rates, pill counts, clinical response monitoring, and electronic monitoring devices.

⑥ The World Health Organization suggests five interactive dimensions to describe factors associated with medication adherence: (1) social and economic, (2) healthcare team- and system-related, (3) condition-related, (4) therapy-related, and (5) patient-related factors.

⑦ To improve and sustain good adherence, healthcare interventions and services must overcome barriers to medication adherence and individualize care by considering multiple factors.

BEYOND THE BOOK

BEYOND THE BOOK

Watch "Medication Adherence," (https://edhub.ama-assn.org/steps-forward/module/2702595) a video from the American Medical Association. This video describes the common reasons for medication nonadherence from patients' perspectives. Then, watch the YouTube video from the FDA Drug Info Rounds (pharmacists), "Taking Medications Correctly—Medication Adherence," (https://www.youtube.com/watch?v=Qh84l557-D0) This video provides a glance at strategies for improving medication adherence.

INTRODUCTION

① Based on the World Health Organization (WHO) definition, medication adherence refers to the extent to which an individual takes medications corresponding to the agreed recommendations from a healthcare provider.[1] Good medication adherence indicates a person takes medications as prescribed, with the appropriate dose via the suggested route at the right time.[2] Poor medication adherence is associated with suboptimal or adverse health outcomes.[3]

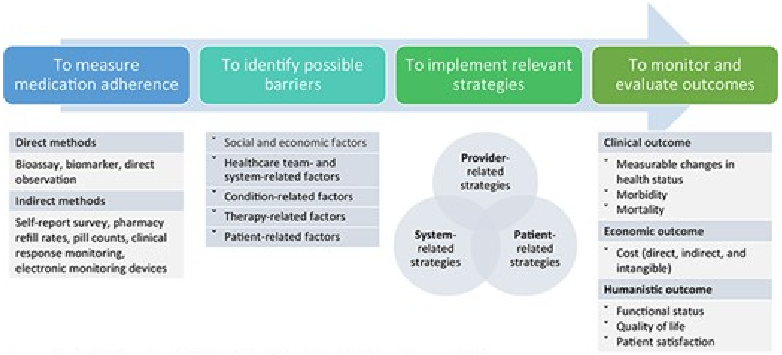
②Compared with nonadherent patients, adherent patients have lower healthcare costs, including fewer hospitalizations and emergency department visits, reduced costs of acute and outpatient care, and better health outcomes and quality of life.[4] For instance, for every patient with type 2 diabetes in an indigent population in Virginia, every 10% increase in medication adherence is estimated to save US $450 annually in medical care[5] and a decrease in glycosylated hemoglobin (HbA_{1c}) level by 0.16% (0.0016; ~1.8 mmol/mol).[6] As a result, medication adherence is widely used as a proxy measure for evaluating disease management and treatment effects.[7]

The estimated rate of medication adherence for chronic illnesses in developed countries is around 50%, even with patients who have easy access to medications.[8] As such, the WHO further indicated that improving medication adherence may have a far greater influence on public health than any improvement in specific medical treatments.[9]

In this chapter, key aspects of the medication adherence process are presented. These include methods of assessment, barriers, and improvement strategies. When the patient is taking the medication as agreed upon, optimal clinical, economic, and humanistic outcomes can be achieved (Fig. e5-1).

FIGURE e5-1

Conceptual framework for assessing and improving medication adherence.



To measure medication adherence
To identify possible barriers
To implement relevant strategies
To monitor and evaluate outcomes
Direct methods
Bioassay, biomarker, direct observation
Indirect methods
Self-report survey, pharmacy refill rates, pill counts, clinical response monitoring, electronic monitoring devices
Social and economic factors
Healthcare team- and system-related factors
Condition-related factors
Therapy-related factors
Patient-related factors
Provider-related strategies
System-related strategies
Patient-related strategies
Clinical outcome
Measurable changes in health status
Morbidity
Mortality
Economic outcome
Cost (direct, indirect, and intangible)
Humanistic outcome
Functional status
Quality of life
Patient satisfaction

MEASURES OF MEDICATION ADHERENCE

③The critical first step in improving medication adherence is to appropriately measure how an individual takes medications as prescribed by healthcare providers. Various methods have been proposed to measure medication adherence; however, there is no agreement among clinical practitioners and researchers on the best method for assessing medication adherence.

Approaches to assessing medication adherence include drug level tests, physiological measures, self-report surveys, pharmacy claims, refill rates, pill counts, clinical response monitoring, and electronic monitoring devices. Each approach to medication adherence evaluation has inherent limitations, and therefore, mixed results were found when integrating these measures into studies. These various approaches are classified as direct and indirect and can be divided into subjective and objective methods.[10]

Direct Methods

④Direct methods of assessing medication adherence include bioassays and biomarkers to measure the level of drug or its metabolite in the body fluid (eg, blood or urine).[11] In addition, direct observation of medication administration is considered a direct approach to medication adherence evaluation.[12]

Direct measures are thought to be the most accurate and can provide physical evidence to prove that the patient has taken the medications. However, direct measures only generate a yes/no result without revealing any patterns or causes of nonadherence. Tests themselves are sometimes intrusive and may cause patients to be anxious and intimidated.[13]

Moreover, direct measures are expensive and require qualified professionals and techniques to perform. Drug-drug and drug-food interactions may hinder the assay accuracy, and plasma drug concentration could vary among individuals with the same dose of the same medication. Biases may also occur if patients know the schedule of the tests and only take medications just before the upcoming tests.[10]

Indirect Methods

⑤ Indirect methods of assessing medication adherence include self-report surveys, pharmacy refill rates, pill counts, clinical response monitoring, and electronic monitoring devices.[12]

Measures involving a secondary claims database could help identify patients at risk for treatment failure based on the pattern of medication refills. Proxy quantitative measures such as medication possession ratio (MPR, defined as the proportion of a given time period when medication supply is available for the patient, assuming that a given refill is all taken as directed) or proportion of days covered (PDC, defined as the proportion of days in a given time period covered by the refills) may be estimated. These methods assume that medication-taking behavior corresponds to the prescription refills and medications are taken as they were prescribed. However, the analysis of a secondary database is limited as it cannot identify partial adherence (eg, occasional missed or incorrect doses) or determine what barriers might have contributed to detected nonadherence (eg, inconvenience of obtaining refills, lack of money for copayments, or out-of-pocket purchases). In addition, claims records can be incomplete in some situations such as when the prescriber or other health professionals advise the patient to early discontinue a drug (temporarily or permanently), or when the medication is obtained through means other than insurance plan.[13]

The Medication Events Monitoring System (MEMS) is a popular form of electronic medication monitoring device that gives a highly accurate assessment of adherence. It comprises a conventional medication container with a special closure that logs the time and date of each opening and closing of the medication container. This electronic device provides a means of keeping track of the number of doses taken as well as the individual pattern of medication taking. Nevertheless, the bulkiness of the container and the high expense of equipment restrict the widespread use of MEMS.[14] In addition, adherence may be overestimated if patients actuate the container by accident or on purpose.[13]

Pill counts calculate the adherence ratio by comparing the number of prescribed dosage units that have been taken to the total number of units received by patients (through initial or refill prescription fills) in a given time period. This method’s low cost, simplicity, and availability in various forms contribute to its popularity. However, this approach is improper for medications used as needed, and it cannot identify the pattern of medication taking or the causes of nonadherence. Also, underestimated adherence may occur due to early refill, and the cutoff value to differentiate adherence and nonadherence is arbitrary.

Unlike many other methods of measuring adherence, self-report surveys are cheap, easy to administer, less intrusive, and able to provide information on beliefs and barriers to adherence.[15] In addition, its real-time feedback and flexibility to accommodate different conditions have resulted in its common use in clinical practice.[16] Considerations of using a self-report survey include the ability to understand the questionnaire items, communication skills of interviewers, and the possibility of patients’ overestimation of adherence or desire to report good medication adherence. These factors can bias response accuracy and affect the survey validity.[17]

Since each method has its pros and cons, and thus, none of the methods described is generally accepted as the gold standard of medication adherence measurement for all settings.[11] The selection of an appropriate measure depends on the attributes of each method, how well the method matches the goals, and the resources available for the intended use.[15] For example, PDC has been the most commonly used adherence measure for cardiovascular disease; self-report measures have been used most often in patients with sexually transmitted diseases.[18]

Self-report survey is the most widely adopted method for assessing medication adherence in clinical practice and research.[14] Self-report measures are often used in studies to allow researchers to assess both the extent of nonadherence and patient’s reasons for nonadherence.[15]

Some generic self-report questionnaires were developed specifically for measuring medication taking and have been used to assess medication adherence across a wide range of chronic diseases. These include the Adherence to Refills and Medications Scale (ARMS),[19] Brief Medication Questionnaire (BMQ),[20] Hill-Bone Compliance Scale (HBCS),[21] Medication Adherence Questionnaire (MAQ),[22] Medication Adherence Rating Scale (MARS),[23] Medication Adherence Reasons Scale (MAR-Scale),[24] and Morisky Medication Adherence Scale (MMAS-8).[25] Table e5-1 compares the characteristics of generic self-report medication adherence instruments commonly used in clinical practice and research.

TABLE e5-1

Characteristics of Generic Medication Adherence Instruments

Scale	ARMS	BMQ	HBCS	MAQ	MARS	MAR-Scale	MMAS-8
Number of items	12	3	14	4	10	20	8
Reliability (Cronbach's α)	0.81	0.66	0.65	0.61	0.75	0.85-0.95	0.83
Concept that can be measured	Medication taking as prescribed, refilling medications on schedule	Regimen complexity, forgetfulness	Forgetfulness, adverse effects	Forgetfulness, adverse effects	Forgetfulness, adverse effects, value of medication	Concern beliefs about medication, necessity beliefs in medication, logistic issues of medication taking, forgetfulness	Forgetfulness, logistic issues of medication taking
Validated in patients with low literacy	Yes	No	No	Yes	Yes	Yes	Yes

ARMS, Adherence to Refills and Medications Scale; BMQ, Brief Medication Questionnaire; HBCS, Hill-Bone Compliance Scale; MAQ, Medication Adherence Questionnaire; MARS, Medication Adherence Rating Scale; MAR-Scale, Medication Adherence Reasons Scale; MMAS-8, Morisky Medication Adherence Scale.

FACTORS ASSOCIATED WITH MEDICATION ADHERENCE

⑥ When considering factors related to medication adherence issues, the WHO suggests the following five interacting dimensions: (1) social and economic factors, (2) healthcare team- and system-related factors, (3) condition-related factors, (4) therapy-related factors, and (5) patient-related factors (Table e5-2).[1] These factors interact to determine whether an individual takes medications as prescribed. Having a comprehensive understanding of the factors associated with medication adherence helps healthcare professionals and researchers identify the barriers to medication adherence and aid patients in tackling problems in medication use. Healthcare professionals should pay attention to several significant factors in assisting populations prone to nonadherence.

TABLE e5-2

Common Barriers to Medication Adherence from Literature

Dimension	Barrier to Medication Adherence
Social and economic factors	• Lower socioeconomic status (eg, education, poverty, employment) • Cost and lack of insurance coverage

	• High out-of-pocket drug costs • Lack of caregivers and family social support • Lack of transportation
Healthcare team- and system-related factors	• Inadequate transmittal of information about disease condition and medications • Shortage of time during appointments with general practitioners • Challenges and time constraints on inquiring about medication adherence • Difficulties in obtaining accurate patients' history of medication availability and use at home • Lack of discharge planning, follow-up, or continuity of care • Unsatisfactory skills in coaching self-management • Poor access to care and medications • Inadequate provision of service at patients' locations • Problems with keeping the medication list updated • Poor information technology (IT) systems and ineffective communication within healthcare systems
Condition-related factors	• Status and severity of the disease under treatment • Disease progression or previous treatment failures leading to loss of faith in medical treatment • Depression leading to reduced motivation • Impaired cognitive function limiting correct medication use • Comorbidities leading to changes in functionality (such as self-care, medication taking), mobility, or mental status
Therapy-related factors	• Complex treatment regimen and burden of medication taking • Polypharmacy • Frequent changes in treatment • Delayed onset of beneficial effects • Required treatment duration (temporary, permanent) • Adverse effects
Patient-related factors	• Limited health literacy to navigate health information and make health-related decisions • Inadequate awareness of the illness • Health beliefs about the condition • Lack of understanding of the role of medications, need for treatment, and proper medication-taking behaviors • General and cultural beliefs (eg, stigma) about medications and drug therapy • Concern about adverse effects of medications • Previous experiences with pharmacological treatments • Less trust in advice from healthcare professionals (poor provider-patient relationship) • Forgetfulness • Lack of competence in self-management • Substitution of prescription medications with self-administered medications, dietary supplements, vitamins and minerals, or folk remedies • Independent pausing or stopping medications when feeling asymptomatic • Receiving incorrect medication information from biased sources (eg, media, neighbors)

Social and Economic Factors

Socioeconomic status has been an independent predictor of medication adherence across diseases. For instance, among people with cardiovascular diseases, higher socioeconomic status positively affects medication adherence.[26] Education level has been shown to positively impact medication adherence in this group.[27,28] In addition, some evidence indicated that ethnic minorities, compared with its counterpart, are less adherent to cardiovascular medications.[27] Black patients have been reported to express more concerns about medication use for diabetes management and more concerns about the competence of their physicians than White patients.[29]

Employment status is also a significant factor. For example, having a job positively affects medication adherence among people living with human immunodeficiency virus (HIV).[30,31] Among people taking oral anticancer agents, better financial status positively affects medication adherence.[32,33] Marital status and social support have mixed results on medication adherence across a range of diseases (eg, cardiovascular diseases, HIV, Parkinson's disease, rheumatoid arthritis, and cancers treated with oral medications).[28,30,33–36]

Higher out-of-pocket costs of medications consistently show a negative association with medication adherence.[37,38] Higher patient copayments hamper medication adherence among people across certain chronic diseases.[39] For example, patients with cardiovascular diseases and paying no copayments are more adherent to their medications than those with any copayments.[40] For people with inflammatory arthritis or taking oral anticancer agents, medication costs have always been a burden of medication adherence.[32,41] Programs that reduce patients' out-of-pocket costs for medications increase adherence. For instance, health insurance status is a potential positive influencer on medication adherence.[28,42]

Healthcare Team– and System-Related Factors

A small number of studies have been conducted on the impact of the healthcare team- and system-related factors on medication adherence.[1] Medication distribution systems, reimbursement structure of health services, and patient-provider relationships affect whether patients take medications as prescribed. Mail-service pharmacies provide better access to medications, facilitating adherence to medications.[38] Communications between patients and their providers can also improve medication adherence. Studies show that good patient-provider relationships and effective patient-physician communications positively affect medication adherence.[38,43]

Condition-Related Factors

Condition-related factors include aspects of specific diseases that can affect medication adherence. Condition-related determinants of medication adherence include the severity of symptoms, disease progression, availability of effective treatments, and level of disability.[1] These factors affect how patients perceive the risk associated with disease and the importance of treatment and how they prioritize their decisions about disease management. For instance, people with diabetes sometimes do not take their medications regularly because of insensible symptoms associated with poor control of serum glucose concentrations.[43] In addition, comorbidities (eg, depression and drug- or alcohol-use disorders) can modify patients' medication-taking behaviors. Duration of disease is another condition-related factor, but it has shown inconsistent effects on medication adherence.[28,34,41,44,45]

Therapy-Related Factors

Various therapy-related factors have been identified that can affect medication adherence. The complexity of the medication regimen, duration of treatment, frequent changes in treatment, immediacy of beneficial effects, fear of adverse effects, and the availability of medical support are notable factors associated with medication adherence.[1] The complexity of regimen is determined by several medication factors: type of drug and route of administration, frequency of administration, quantity of daily dosage, forms or length of time required for infusions, and size of solid oral dosage forms. For example, fear of injections deters patients from taking insulin products for diabetes care.[38] In addition, a need for numerous daily administrations, swallowing too many tablets or capsules or large amounts of liquid medications, and large size of some tablets and capsules make it difficult for patients to take medications as prescribed.[43]

Patient-Related Factors

Patient-related factors include the demographics, knowledge, attitudes, beliefs, perceptions, and expectations of the patient.[1]

Ample research has investigated the effect of patients' demographics on medication adherence, but findings have been inconsistent. Some evidence found older populations report better medication adherence among people with cardiovascular conditions,[46] HIV,[47] and Parkinson's diseases.[35] In contrast, a few studies on anticancer agents found better medication adherence among people of younger ages.[34] A gender effect was noted on medication adherence among people with cardiovascular disease, with higher medication adherence in women.[27] Nonetheless, a few other studies found that there was no difference in medication adherence rate due to gender effects.[32,35,48]

While inherent characteristics associated with medication adherence may be difficult to change in clinical practice, some patient-related factors that affect medication adherence can be addressed to improve medication adherence. Several studies have indicated that patients' knowledge and perceptions about their diseases affect medication adherence, so does the motivation to control disease and patients' confidence in achieving needed changes in disease-management behaviors.[1] For example, medication adherence among people with mental diseases is associated with health beliefs and psychological personalities, such as self-efficacy, disease perception, and locus of control.[49] Medication-taking behaviors among people with breast cancer are affected by their knowledge of the disease, perceptions of the balance between risks and benefits of treatment, and confidence in coping with disease management.[50] Healthcare professionals should be more attentive when treating specific populations who are prone to medication nonadherence and provide tailored interventions to modify their medication beliefs and behaviors.

Of note, health literacy is positively associated with medication engagement among people with diabetes or chronic obstructive pulmonary disease (COPD).[51,52] Health literacy is an individual's ability to obtain, process, understand, and apply the information about interventions in making an appropriate health-related decision.[53] People with diabetes need to understand readings on a glucose meter and adjust their medications accordingly.[54] Similarly, people with COPD need to gauge the number on a peak flow meter to know if the disease is under proper control.[52]

Forgetfulness, psychosocial stress, concerns about possible adverse effects, low motivation, inadequate knowledge and skill in disease management, and negative beliefs in medications have been reported as barriers to adherence to the prescribed medication. Factors that improve medication adherence include greater understanding of the disease, positive perception of health risk related to the disease, complete comprehension of treatment instructions, being well-informed about disease monitoring, keeping appointments for follow-up or counseling, and perceiving greater autonomy regarding disease management.[43]

Subsequent to research into these factors, healthcare professionals can tailor their intervention by accounting for patients' psychosocial factors and thereby changing their medication-taking behaviors. The time constraint of clinic visits has been recognized as one of the main factors hampering the delivery of effective interventions; however, healthcare providers may strategically address modifiable factors to improve medication adherence in clinical practices. Building on a patient's intrinsic motivation by increasing the perceived importance of adherence and strengthening confidence by building self-management skills are behavioral treatment targets that must be addressed concurrently with biomedical ones if overall adherence is to be improved.[1]

STRATEGIES FOR IMPROVING MEDICATION ADHERENCE

Numerous strategies for improving patients' adherence to antidiabetic medications have been proposed, including easier access to medication, provision of printed or digital materials, and use of medication reminders.[4] However, the increase in medication adherence rates has been limited and less than expected.[55]

⑦ The multidimensional nature of nonadherence is one of the reasons that no single strategy is effective across all conditions and settings.[56] For instance, a multidisciplinary approach addresses multiple factors associated with medication nonadherence.[56] The framework recognized that medication nonadherence involves not only patient and provider issues but also system problems. It provides a SIMPLE strategy to improve medication adherence in clinical practice by (1) ***S***implifying regimen characteristics, (2) ***I***mparting knowledge, (3) ***M***odifying patient beliefs, (4) ***P***atient communication, (5) ***L***eaving the bias, and (6) ***E***valuating adherence.[56] Hence, to improve and sustain adherence, interventions must account for barriers to medication adherence and address multiple factors.[57] Multifactorial solutions include efforts to improve patients' understanding of medication benefits and increase access and trust in their providers and the health system in general (Table e5-3).

TABLE e5-3

Examples of Strategies for Improving Medication Adherence

Aspect	Strategy
Provider related	• Understanding patients' values, preferences, disease perceptions, and behaviors towards management • Developing trust and rapport with patients and healthcare stakeholders • Considering patients' schedules when prescribing medication • Simplifying the amount of medications and dosing frequency • Medication counseling for patients and caregivers; checking and teaching the right use of medications and medical devices • Supplying appropriate adherence aids or providing reminders • Pharmacists as coaches for drug therapies • Mental health screening and support
Patient related	• Focusing on health outcomes of self-management and drug therapies • Support for patients to better understand their disease and its management • Support from caregivers • Peer groups for chronic conditions, and training in peer groups • Using reminder devices or text messages
System related	• Interprofessional practices for updating the drug lists • Interprofessional practices and interventions, such as medication reconciliation, medicine optimization, and medication review • Continuity of care and permanent doctor-patient relationships • Equal partnerships with patients, with a coaching attitude • Setting achievable goals • Healthcare-wide patient information sharing and better IT systems

Provider-Related Strategies

Improving providers' recognition and understanding of patients' beliefs, difficulties, fears and values, as well as their own biases, are necessary to achieve increased medication adherence and better health.[9]

Each healthcare professional engaged in patient care (eg, physicians, pharmacists, nurses, case managers, and health educators) understands and respects one another's responsibilities and roles. For example, understanding and accepting pharmacist's role in imparting medication-related information to patients may help clinicians focus on other aspects of treatment plans.[56] Trained pharmacists are equipped with full skillsets to overcome the asymmetric knowledge gap between patients and healthcare professionals, enhance shared decision making, and provide strategies to empower patients to have regular medication-taking.[58] Pharmacists can provide comprehensive drug information, identify potential adverse drug reactions, and supply appropriate adherence aids to help patients adhere to their medication regimens. Other healthcare staff can mail or text reminders and provide social support to ease adherence-related hurdles that patients may encounter.

In addition, telehealth interventions have positively affected medication adherence among people with rheumatoid arthritis.[59] In addition to traditional printed educational materials and face-to-face interactions, the application of advanced technology can facilitate adherence to medication using diverse formats based on patients' preference (eg, generation differences, lifestyle issues) and geographical feasibility (eg, remote communication, pandemic hindrance, and transportation issues).

Patient-Related Strategies

Motivational interviews are found to improve medication adherence among people with cardiovascular conditions.[60,61] This counseling technique enhances individuals' motivation to change their behaviors by means of four principles, denoted by the acronym RULE: ***R***esist the righting reflex, ***U***nderstand the patient's motivations, ***L***isten with empathy, and ***E***mpower the patient.[62] Interviewers help patients link medication use to the task that patients deem the most important, motivating patients to achieve the goal they set through improved adherence to medications.

Some research into chronic diseases has addressed modifiable determinants of medication adherence in interventions and shown positive effects on adherence.[63] A few studies incorporated several psychological factors to increase medication adherence by strengthening patients' beliefs in medications, comprehensive perceptions of illness, stronger confidence in disease management, and alleviating concerns about medication use.[57,64] For people with HIV, some interventions used medication schedule reminders and treatment support through electronic platforms to facilitate better medication adherence.[65,66]

Other interventions help providers improve their communications with patients about medication taking. Perceptions of disease and treatment can be shaped differently because of cultural differences. Some interventions have been adopted to improve medication adherence in patients with ethnically diverse backgrounds.[29,67] Moreover, several studies have identified ways to improve medication adherence through peer coach approaches, in which patients share experiences and learn from each other.[68] As patients come from similar communities and social backgrounds, they easily relate one another's barriers to optimize disease management and control, empowering patients through greater internal motivation.[69]

System-Related Strategies

When addressing medication adherence through policymaking and reform of healthcare system, time is needed to discuss options and negotiate across different sectors. Confidentiality-ensured healthcare-wide patient information sharing and better information technology (IT) systems could facilitate information circulated seamlessly among the healthcare team. Provision of continuity of care with close interprofessional collaboration may make the process of patient care delivery more consistent and sustainable. Development of equal partnerships with patients could foster strong rapport between providers and patients. A growing body of intervention research guided by psychosocial behavioral models focuses on tailoring individual and interpersonal factors to improve patients' awareness, attitudes, and behaviors related to medication taking.[70] Stakeholders of healthcare system need to set achievable goals and check the progress accordingly to better allocate available resources for improved medication adherence.

CONCLUSION

Medication adherence is critical to improving health outcomes. Assessing adherence to medical treatment is important to clinicians and researchers but various measures all have inherent limitations. Successful attempts to improve patient adherence depend on a set of key factors. To optimize medication adherence, the multifactorial causes of decreased adherence must be understood. Patients should be involved in treatment plans, and personalized approaches tailored to each patient's issues should be taken to improve and sustain adherence.

ABBREVIATIONS

ARMS	Adherence to Refills and Medications Scale

SELF-ASSESSMENT QUESTIONS

1. Which of the following is not an example of patient medication nonadherence?

   A. Incorrect inhaler technique

   B. Unintentional dose omission

   C. Adjusting the daily dose of a medication without a logical reason

   D. Discontinuing PRN medication

2. Which of the following outcomes is most likely to occur in patients with poor medication adherence?

   A. Lower healthcare costs

   B. Fewer emergency department visits

   C. Increased costs of acute care

   D. Better quality of life

3. Which of the following is a direct approach to measure medication adherence?

   A. Using a self-report survey

   B. Measuring drug metabolites in urine

   C. Calculating the pharmacy refill rate from a claims database

   D. Counting the pills remaining in the pill box in a given time period

4. Which of the following is an indirect method to evaluate medication adherence?

   A. Analyzing drug concentrations in the blood

   B. Watching patients swallow every dose of prescribed medications

   C. Measuring drug metabolites in urine

   D. Using electronic devices to keep track of exact medications taken by patients

5. Which of the following is the *most widely* adopted indirect approach to assessing medication adherence in clinical practice?

   A. Administering self-report survey

   B. Calculating pills left in the pill box

   C. Measuring the levels of drug metabolites in urine

   D. Using the Medication Events Monitoring System to trace medications taken by patients

6. Which of the following is the *most appropriate* way to describe the characteristics of various approaches to assessing medication adherence?

   A. Analysis of a secondary database can determine the exact reasons for medication nonadherence.

   B. Overestimated medication adherence may occur due to early refill when using pill counts to calculate the adherence ratio.

   C. The Medication Events Monitoring System is a low-cost device to accurately assess medication adherence.

   D. The use of self-report surveys can provide information on barriers to medication adherence.

7. Inadequate provision of medication counseling belongs to which of the following dimensions associated with medication adherence?

   A. Social and economic factors

   B. Healthcare team– and system-related factors

   C. Therapy-related factors

   D. Patient-related factors

8. A complex treatment regimen belongs to which of the following dimensions associated with medication adherence?

   A. Healthcare team– and system-related factors

   B. Condition-related factors

   C. Therapy-related factors

   D. Patient-related factors

9. Which of the following barriers to medication adherence is a social factor?

   A. Inadequate interaction time with general practitioners

   B. Limited health literacy to make health-related decisions

   C. Lack of social support from family

   D. Less trust in advice from healthcare professionals

10. Impaired cognitive function may limit correct medication use. Into which of the following categories of factors medication nonadherence does that situation fall?

    A. Healthcare team–related factors

    B. Healthcare system–related factors

    C. Condition-related factors

    D. Therapy-related factors

11. Which of the following barriers is not a condition-related factor associated with medication nonadherence?

    A. Impaired cognitive function

    B. Previous experience of treatment failure

    C. Depression and reduced motivation

    D. Patients' health beliefs about the disease condition

12. Patients are more likely to become nonadherent to which of the following treatments?

    A. Albuterol to prevent an asthma attack

    B. Imatinib to treat chronic myelogenous leukemia

    C. Enalapril to treat hypertension

    D. Diphenhydramine to relieve cold symptoms

13. To help improve medication adherence, which of the following patient-related factors is *most modifiable*?

    A. Understanding the treatment need

    B. Having a low level of education

    C. Changing social norms about certain drug therapies

    D. Being an old person

14. Which of the following activities is *most likely* to help a patient with diabetes understand the readings on a glucose meter and appropriately adjust the dose of insulin?

    A. Gaining more knowledge of insulin per se

    B. Empowering adequate health literacy in diabetic self-care

C. Equipping more concerns about adverse effects of insulin

D. Participating in discussions with peers with negative beliefs about medications

15. Which of the following strategies is related to providers for improving medication adherence?

A. Providing patient information sharing throughout healthcare

B. Participating in peer groups for the management of chronic diseases

C. Facilitating the support of caregivers

D. Developing trust and rapport with patients and healthcare stakeholders

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** Medication adherence is defined as the extent to which patients are able to follow the recommendations for prescribed treatments. Medication nonadherence may be intentional or unintentional, and patients' reasons for deviating from the (agreed) treatment plan are diverse. Patients may decide not to fill their prescriptions in the pharmacy or not start their treatment at all. Patients may use more or less than the prescribed treatment and use their medication at the wrong time or in the wrong way. They may also discontinue treatment prematurely. See the Introduction section of Chapter e5 for more information.

2. **C.** Compared with nonadherent patients, adherent patients have lower healthcare costs (including fewer hospitalizations and emergency department visits), reduced costs of acute and ambulatory care, and better health outcomes and quality of life. See the Introduction section of Chapter e5 for more information.

3. **B.** Direct methods for assessing medication adherence include bioassays and biomarkers to measure the level of a drug or its metabolite in body fluids (eg, blood or urine). In addition, direct observation of medication administration is considered a direct approach to assessing medication adherence. See the section on "Measures of Medication Adherence (Direct Methods)" in Chapter e5 for more information.

4. **D.** Indirect methods for assessing medication adherence include self-report surveys, pharmacy refill rates, pill counts, clinical response monitoring, and electronic monitoring devices. See the section "Measures of Medication Adherence (Indirect Methods)" in Chapter e5 for more information.

5. **A.** Currently, self-report survey is the most widely adopted method for assessing medication adherence in clinical practice and research. See the section "Measures of Medication Adherence (Indirect Methods)" in Chapter e5 for more information.

6. **D.** Analysis of a secondary database is limited, as it cannot identify partial adherence (eg, occasionally missed or incorrect doses) or determine what barriers might have contributed to detected nonadherence (eg, inconvenience of obtaining refills, lack of money for copayments or out-of-pocket expenses). The bulkiness of the container and the high expense of equipment restrict widespread use of the Medication Events Monitoring System. Underestimated medication adherence can occur due to early refill when using pill counts to calculate the adherence ratio. See the section "Measures of Medication Adherence" in Chapter e5 for more information.

7. **B.** The patient-provider relationship is one of the factors related to the healthcare team and system that impacts adherence to medications. Studies have shown that good patient-provider relationships and effective patient-physician communication positively affect medication adherence. See the "Factors Associated with Medication Adherence" section and Table e5-2 for more information.

8. **C.** Various therapy-related factors have been identified that affect medication adherence. The complexity of the medication regimen, duration of treatment, frequent changes in treatment, immediacy of beneficial effects, and drug-related adverse effects are notable factors associated with medication adherence. See the "Factors Associated with Medication Adherence" section and Table e5-2 for more information.

9. **C.** Socioeconomic status has been an independent predictor of medication adherence across diseases. Lack of social support from caregivers and family is also one of the social factors associated with medication adherence. See the "Factors Associated with Medication Adherence (Social and Economic Factors)" section and Table e5-2 for more information.

10. **C.** Condition-related factors include aspects of specific diseases that can affect medication adherence. Condition-related determinants of medication adherence include the severity of symptoms, disease progression, availability of effective treatments, and level of disability. See the "Factors Associated with Medication Adherence" section and Table e5-2 for more information.

11. **D.** Health beliefs about the disease condition are patient-related factors of medication nonadherence. Adherence is highly correlated with patients' beliefs about severity of the disease to be prevented or treated. See the "Factors Associated with Medication Adherence" section and Table e5-2 for more information.

12. **C.** Patients most often become nonadherent to chronic diseases, such as hypertension, where they do not have any unpleasant symptoms even without strict adherence to medication regimens. Studies have shown that adherence rates may drop dramatically when medication is taken over a long period for disease prevention or cure. See the "Factors Associated with Medication Adherence (Condition-Related Factors)" section and Table e5-2 for more information.

13. **A.** Although the inherent characteristics associated with medication adherence may be difficult to change in clinical practice, some patient-related factors that affect medication adherence can be addressed to improve medication adherence. Educating patients to understand the purpose and need of treatment is one of the important strategies to improve medication adherence. See the "Factors Associated with Medication Adherence (Patient-Related Factors)" section in Chapter e5 for more information.

14. **B.** Health literacy is an individual's ability to obtain, process, understand, and apply information about interventions to make an appropriate health-related decision. People with diabetes need to understand the readings on a glucose meter and adjust their medications accordingly. See the "Factors Associated with Medication Adherence (Patient-Related Factors)" section in Chapter e5 for more information.

15. **D.** Studies have shown that good patient-provider relationships and effective patient-physician communication positively affect medication adherence. See the "Strategies for Improving Medication Adherence (Provider-Related Strategies)" section and Table e5-3 for more information.

Chapter e6: Clinical Pharmacokinetics and Pharmacodynamics

Kristin M. Janzen; Samuel M. Poloyac

KEY CONCEPTS

KEY CONCEPTS

① Clinical pharmacokinetics is the discipline that describes the absorption, distribution, and elimination of medications in patients requiring pharmacotherapy.

② The pharmacokinetic parameter that describes absorption is the bioavailability. Bioavailability refers to the proportion of the dose of a medication that reaches systemic circulation.

③ The pharmacokinetic parameter that describes distribution is the volume of distribution. The volume of distribution is a proportionality constant that relates the amount of medication in the body to the serum concentration.

④ To characterize differences in drug distribution, we can use compartmental models to describe the different behaviors. Compartmental models are mathematical descriptions of the grouped body spaces that the medication penetrates and the overall time it takes to get into each space.

⑤ The pharmacokinetic parameter that describes elimination is clearance. Clearance describes the volume of plasma cleared of the given drug over time, and it may be either linear or nonlinear.

⑥ Most drugs follow linear pharmacokinetics, in which serum drug concentrations change proportionally with changes in dose.

⑦ Some drugs do not follow the rules of linear pharmacokinetics, which leads to a variety of nonlinear pharmacokinetic profiles. Instead of concentration increasing proportionally with dose, serum concentrations change more or less than expected.

⑧ The pharmacokinetic parameter that describes the time required for serum concentrations to decrease by one-half is half-life. Half-life is dependent on the values of clearance and volume of distribution.

⑨ Pharmacokinetic models are useful to describe data sets, to predict serum concentrations after several doses or different routes of administration, and to calculate pharmacokinetic constants such as clearance, volume of distribution, and half-life.

⑩ Many factors should be taken into consideration when deciding on the best drug dose for a patient. These include patient-specific factors, including age, sex, weight, race/ethnic background, genetics, other concurrent disease states, kidney function, and hepatic function, as well as drug-specific factors (drug-drug interactions, drug-food interactions).

⑪ Cytochrome P450 enzymes are responsible for most drug metabolism oxidation reactions.

⑫ Membrane transporters are protein molecules that actively transport drugs across cell membranes. Transport proteins are important in the processes of drug bioavailability, elimination, and distribution.

⑬ When deciding on initial doses for drugs that are renally eliminated, the patient's kidney function should be assessed. A common, useful way to do this is to measure the patient's serum creatinine concentration and convert this value into an estimated creatinine clearance (CL_{cr}).

⑭ When deciding on initial doses for drugs that are hepatically eliminated, the patient's liver function should be assessed. The Child-Pugh score can be used as an indicator of a patient's ability to metabolize drugs that are eliminated by the liver.

⑮ For drugs that exhibit linear pharmacokinetics, steady-state drug concentration changes proportionally with dose.

⑯ Some drugs with narrow therapeutic windows require determination of the pharmacokinetic constants to individualize the patient's dose. In these cases, a small pharmacokinetic evaluation is conducted in the individual.

⑰ Pharmacodynamics is the study of the relationship between the concentration of a drug and the response obtained in a patient. If pharmacologic effect is plotted against concentration for most drugs, a hyperbola results with an asymptote equal to the maximum attainable effect. The potency of a drug is estimated by the concentration required to achieve 50% of that maximal effect.

BEYOND THE BOOK

BEYOND THE BOOK

Watch the video titled “Introduction to Pharmacokinetics”, available at https://www.youtube.com/watch?v=TwSsMHtfQD4. This video provides a brief overview of basic pharmacokinetic concepts. This website is useful to enhance student understanding of basic pharmacokinetic concepts.

INTRODUCTION

Pharmacokinetic concepts have been used successfully to individualize pharmacotherapy and optimize patient care since the 1970s. Clinical pharmacists provide patient-specific drug-dosing recommendations that increase the efficacy and decrease the toxicity of many medications as a part of routine patient care responsibilities. Laboratories measure patient serum or plasma samples for many drugs, including antibiotics (eg, aminoglycosides and vancomycin), antiepileptics (eg, phenytoin, carbamazepine, valproic acid, and phenobarbital), methotrexate, lithium, antiarrhythmics (eg, lidocaine and digoxin), and immunosuppressants (eg, cyclosporine and tacrolimus). The process of measuring serum concentrations and using the results to optimize dose regimens is called therapeutic drug monitoring.[1] As practice has continued to evolve, the role of pharmacists in a variety of patient care settings has changed to include provision of therapeutic drug monitoring services through collaborative practice agreements and institutional protocols.[2] However, the entire healthcare team is necessary to ensure therapeutic drug monitoring is utilized appropriately.[1] As such, it is more important now than ever for the healthcare practitioner to understand and be able to apply pharmacokinetic and pharmacodynamic principles to practice.

Combined with a knowledge of the disease states and conditions that influence the disposition of a particular medication, kinetic concepts can be used to modify doses to produce serum drug concentrations that result in desirable pharmacologic effects without unwanted side effects. This range of concentrations within which the pharmacologic response is produced and adverse effects prevented in most patients is referred to as the therapeutic range or the therapeutic window of a given medication. Table e6-1 lists the therapeutic ranges for selected medications. Although most individuals experience favorable effects with serum drug concentrations in the therapeutic range, the effects of a given serum concentration can vary widely among individuals. Clinicians should never assume that a serum concentration within the therapeutic range will be safe and effective for every patient. The response to the medication, such as the number of seizures while taking an antiepileptic agent, should always be assessed as the primary measure of efficacy with serum concentrations used as an additional informative measure.

TABLE e6-1

Selected Therapeutic Ranges

Drug	Therapeutic Range
Digoxin	0.5-2 ng/mL or mcg/L
	0.6-2.6 nmol/L
Gentamicin, tobramycin[a]	5-10 mcg/mL or mg/L (peak)
	10-21 µmol/L (peak)
	<2 mcg/mL or mg/L (trough)
	<4 µmol/L (trough)
Lithium	0.6-1.4 mEq/L
	0.6-1.4 mmol/L
Carbamazepine	4-12 mcg/mL or mg/L
	17-51 µmol/L
Phenobarbital	15-40 mcg/mL or mg/L
	65-172 µmol/L
Phenytoin/Fosphenytoin	10-20 mcg/mL or mg/L
	40-79 µmol/L
Valproic acid	50-100 mcg/mL or mg/L
	347-693 µmol/L
Cyclosporine (blood)	150-400 ng/mL or mcg/L
	125-333 nmol/L

[a] Using a multiple dose per day conventional dosage schedule.

Pharmacokinetic and pharmacodynamic principles are essential for selecting the appropriate dose, route, and frequency of pharmacotherapy in order to maximize efficacy and minimize adverse drug effects for both populations and individual patients.

PHARMACOKINETIC PRINCIPLES

① Clinical pharmacokinetics is the discipline that describes the absorption, distribution, and elimination of medications in patients requiring pharmacotherapy. In order to describe how a medication behaves in a patient, one must first define several characteristics of the medication's concentration-time profile. These characteristics are called pharmacokinetic parameters and are used to determine the optimal dose and interval for a given medication. Each of these concepts will be discussed in turn.

Absorption

When a medication is administered extravascularly to patients, it must be absorbed across biologic membranes to reach the systemic circulation. If the medication is given orally, the drug molecules must pass through the gastrointestinal (GI) tract wall into capillaries. For transdermal patches, the medication must penetrate the skin to enter the vascular system. In general, the pharmacologic effect of the medication is delayed when it is given extravascularly because time is required for the medication to be absorbed from the administration site into the vascular system and distributed to the tissue site of action.

② The pharmacokinetic parameter that describes the extent of absorption is the bioavailability. Bioavailability (F) refers to the proportion of the dose of a medication that reaches systemic circulation. For medications administered intravascularly, 100% of the dose enters into circulation and F equals 1. For medications administered via different routes (oral, transdermal, etc.), it is common that some of the medication fails to enter circulation, either via incomplete absorption due to low permeability or solubility, metabolism by enzymes in the GI tract or liver before the medication reaches systemic circulation or secretion of the medication back into the GI tract via transport proteins.[3,4] In this case, F would be less than 1, as less than 100% of the medication reaches systemic circulation.

Distribution

The vascular system generally provides the “transportation” for the drug molecule to its site of activity. After the medication reaches the systemic circulation, it can leave the vasculature and penetrate the various tissues or remain in the blood. If the medication remains in the blood, it may bind to endogenous circulating blood proteins, such as albumin and α1-acid glycoprotein. This binding usually is reversible, and an equilibrium is created between protein- bound drug and unbound drug. Unbound drug in the blood provides the driving force for distribution of the agent to body tissues. If unbound drug leaves the bloodstream and distributes to tissue, it may become tissue-bound, it may remain unbound in the tissue, or if the tissue can metabolize or eliminate the drug, it may be rendered inactive and/or eliminate the drug from the body. If the drug becomes tissue-bound, it may bind to the receptor that causes its pharmacologic or toxic effect or to a nonspecific binding site that causes no effect. Again, tissue binding is usually reversible, so that the tissue-bound drug is in equilibrium with the unbound drug in the tissue.

③ The pharmacokinetic parameter that describes the apparent drug distribution is the volume of distribution. The volume of distribution (V_D) is a proportionality constant that relates the amount of drug in the body to the serum concentration (C). The volume of distribution can be calculated by dividing the amount of medication administered (dose) by the initial concentration achieved (C_0):

$$V_D = \frac{\text{dose}}{C_0}$$

VD = doseC0

Conversely, if a given concentration is being targeted to achieve an effect, then the dose can be calculated by multiplying the targeted C_0 by the medication's estimated volume of distribution. This is known as the loading dose (LD) of a medication and can be calculated using the following equation:

$$\text{Loading dose} = C_0 V_D$$

Loading dose = C0VD

In practice, the patient's own V_D is not known at the time the loading dose is administered. In this case, an average V_D is assumed based on population studies. The estimated V_D can be used to calculate an expected serum concentration after a weight-based loading dose is given or can be used to calculate a loading dose to obtain a desired C_0; however, it should be noted that the patient's actual V_D is almost always different from the average V_D for the medication. As such, a loading dose does not usually attain the calculated C_0, but it does ideally achieve a therapeutic concentration. Of note, steady-state conditions are achieved in 3 to 5 half-lives for the medication.

The numeric value for the volume of distribution is determined by the physiologic volume of blood and tissues and how the drug binds in blood and tissues[5]:

$$V_D = V_b + \left(\frac{f_{ub}}{f_{ut}}\right) V_t$$

VD = Vb + (fubfut)Vt

where V_b and V_t are the volumes of blood and tissues, respectively, and f_{ub} and f_{ut} are the fractions of unbound drug in blood and tissues, respectively. This is a useful pharmacokinetic equation in that it related the unbound fraction of the drug to the volume of distribution. For example, if the f_{ub} increases, the V_D increases because more drug is now free to distribute to the tissues. Conversely, if the f_{ut} increases, then V_D decreases because drug is not being bound in the tissues as extensively and is free to distribute back into the central circulation.

④ Another way to characterize a medication's pharmacokinetic behavior is by evaluating the distributional characteristics of the medication after administration. For some medications the distribution into the tissues is very rapid relative to the overall time it takes for elimination. For other medications, there is a lag or delay in the time that it takes for the blood and the body tissues to equilibrate. To characterize differences in drug distribution, we can use compartmental models to describe the different behaviors. Compartmental models are mathematical descriptions of the grouped body spaces that the medication penetrates and the overall time it takes to get into each space. For example, the blood and tissues that are easily perfused will often be grouped into the central compartment because the equilibration happens rapidly after administration. Some medications only enter easily or rapidly perfused tissue; therefore, a single compartment (one compartment model) can be used to describe the drugs distributional behavior. In contrast, some medications may distribute into harder to perfuse tissues as well, such as the brain, muscle, and/or adipose tissue. If a medication has both rapid central compartment with easily perfused tissue and also gets into harder to perfuse tissues, then the medication's distribution may be best characterized by a multiple compartmental model. Overall, compartmental models are used as an oversimplification of the complexity of a medication's pharmacokinetic behavior; however, this oversimplification allows for the use of basic mathematical concepts that can assist in estimating a medication's concentration, dose, and overall pharmacokinetic behavior.

One Compartment Model

For the simplest case, a single compartment can describe the drug's distribution to the entire body (see Fig. e6-1). The medication can be administered and enter the central compartment by intravenous (IV) bolus dosing (D_{iv}), by rate of zero order IV infusion (R_0), or by absorption from an extravascular site with an absorption rate constant of k_a (D) depending on the route of administration. If the medication has one compartment model distribution characteristics, then the medication reaches a very rapid distribution in all of the tissues into which the medication will distribute. In this case, the time from when the medication is administered until the first blood sample is drawn is enough time that the medication has reached equilibration with all of the tissues to which it is distributed. In this case, the medication concentrations will decrease in a monoexponential fashion as long at the medication has first-order, concentration dependent (linear) pharmacokinetic characteristics, which will be described later in this chapter.

FIGURE e6-1

Representative serum concentration-time curves following intravenous or extravascular dosing.

Multiple Compartment Model

For medications whose pharmacokinetics follow multicompartment distribution, additional time is needed for some of the tissues to reach equilibration, which can be observed in the initial phase of the medication's concentration time profile (Fig. e6-1). Again, the medication can be administered and enter the central compartment by IV bolus dosing (D_{iv}), by continuous IV infusion (R_0), or by absorption from an extravascular site with an absorption rate constant of k_a (D) depending on the route of administration. The systemic blood circulation as well as the highly perfused and rapidly distributed tissues will make up the central compartment as with the one compartment model. However, for multicompartment drugs, there are other body tissues that require additional time to reach equilibration with the blood for distribution. These harder to perfuse tissues are considered in the peripheral compartment. There can be several different peripheral compartments depending on the complexity of a given medication's pharmacokinetic behavior. For a two compartmental model drug, there is a central, easy to perfuse blood/tissue compartment and single, hard to perfuse tissue compartment that describe the medication's behavior. As such, two different V_D values are needed to describe the serum-concentration-versus-time curve, which include the central compartment volume (V_c) and the volume of distribution after tissue distribution (V_{area}).

At the early time points after administration, drug is being both distributed (prior to equilibration in hard to perfuse tissues) and eliminated. This creates a biexponential decrease in the drug concentration over time. If elimination is still the slowest overall rate for this two-compartmental drug, then over time, the hard to perfuse tissues and blood will eventually reach a point of equilibrium, which is known as pseudoequilibrium. At this point, the medication has equilibrated with all tissues and will follow a mono-exponential decline with time.

Elimination

⑤ Elimination is the process in which the body clears the medication from the body, which may occur through metabolism and/or excretion. The pharmacokinetic parameter that describes elimination is clearance. Clearance describes the volume of plasma cleared of the given medication over time, and it may be either linear or nonlinear. Clearance (CL) is the most important pharmacokinetic parameter because it determines the steady-state drug concentration (C_{SS}) for a given dosage, which is essential in maintaining the targeted therapeutic concentration of a drug in a patient and determining the appropriate maintenance dose (MD).

Clearance includes two main strategies: metabolism and excretion. Certain organs—such as the liver, GI tract wall, and lung—possess enzymes that metabolize drugs. The resulting metabolite may be inactive or have a pharmacologic effect of its own. The blood also contains esterases, which cleave ester bonds in drug molecules and generally render them inactive. Drug metabolism usually occurs in the liver through one or both of two types of reactions. Phase I reactions generally make the drug molecule more polar and water soluble so that it is prone to excretion by the kidney. Phase I modifications include oxidation, hydrolysis, and reduction. Phase II reactions involve conjugation to form glucuronides, acetates, or sulfates. These reactions generally inactivate the pharmacologic activity of the drug and may make it more prone to ultimate elimination by the kidney. Other organs have the ability to eliminate drugs or metabolites from the body. The kidney can excrete drugs by glomerular filtration or by such active processes as proximal tubular secretion. Drugs can also be excreted via bile produced by the liver or by air expired by the lungs.

Clearance can be described mathematically as follows:

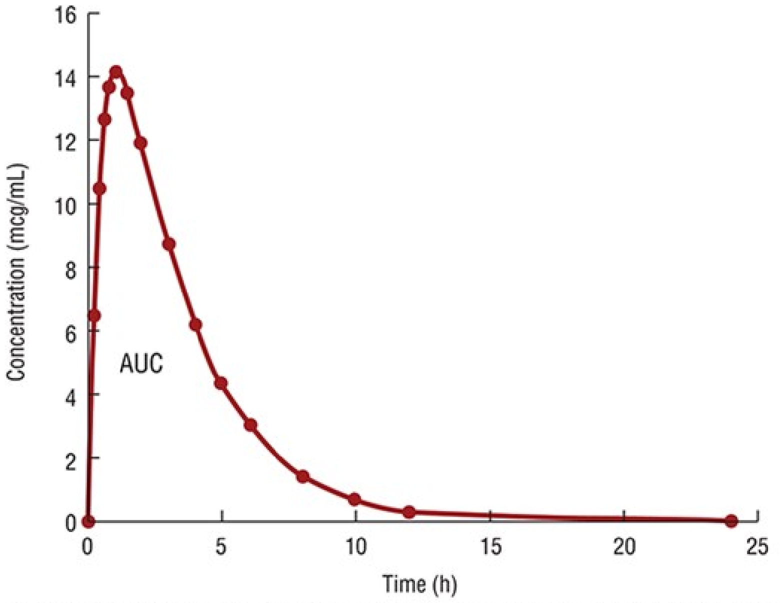
$CL = {}^{\Delta A}/_{\Delta t}/_{C}$ CL = ΔAΔtC

where clearance is equal to the elimination rate (ΔA/Δt) divided by the plasma concentration. As such, clearance is inversely proportional to concentration—when clearance increases, plasma concentration decreases. Clearance can also be defined in terms of dose and area under the curve (AUC). The AUC represents the body's total exposure to the drug over time (Fig. e6-2). When the rate divided by concentration is integrated from 0 to infinity (∞), the amount from 0 to ∞ is equal to the dose. When the concentration multiplied by change in time is integrated from 0 to ∞, the result is the AUC. This results in the integrated equation:

$CL = D/AUC_0^\infty$ CL = DAUC0∞

FIGURE e6-2

Area under the concentration-versus-time curve (AUC) after the administration of an extravascular dose in a two-compartment model. The AUC is a function of the fraction of drug dose that enters the systemic circulation and clearance.



Source: Joseph T. DiPiro, Gary C. Yee, L. Michael Posey, Stuart T. Haines, Thomas D. Nolin, Vicki L. Ellingrod: *DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e*

where clearance is equal to the dose divided by AUC. In practice, AUC is rarely measured directly due to the need for intensive blood sampling for accurate calculation. Instead, if the clearance of a given drug is known, the AUC can be calculated using:

$AUC = \frac{D}{CL}$ AUC = DCL

Clearances for Different Routes of Elimination and Metabolic Pathways

When a medication is given as a continuous IV infusion at a rate equal to R_0, the C_{ss} is determined by the quotient of R_0 and CL ($C_{ss} = R_0/\mathrm{CL}$). If the medication is administered as individual doses (D) at a given dosage interval (τ), then the average C_{ss} over the dosage interval is given by the equation[6]:

$$C_{ss} = \frac{F\left(\frac{D}{\tau}\right)}{\mathrm{CL}}$$

Css = F(Dτ)CL

where F is the fraction of dose absorbed into the systemic vascular system. The average C_{ss} over the dosage interval is the C_{ss} that would have occurred had the same dose been given as a continuous IV infusion (eg, 300 mg every 6 hours would produce an average C_{ss} equivalent to the actual C_{ss} produced by a continuous infusion administered at a rate of 50 mg/hr).

Physiologically, clearance is determined by (1) blood flow (Q) to the organ that metabolizes (liver) or excretes (kidney) the medication, and (2) the efficiency of the organ in extracting the medication from the bloodstream. Efficiency is measured using an extraction ratio (E), calculated by subtracting the concentration in the blood leaving the extracting organ (C_{out}) from the concentration in the blood entering the organ (C_{in}) and then dividing the result by C_{in}:

$$E = \frac{C_{\text{in}} - C_{\text{out}}}{C_{\text{in}}}$$

E = Cin−CoutCin

Clearance for that organ is calculated by taking the product of Q and E (CL =QE). For example, if liver blood flow equals 1.5 L/min, and the drug's extraction ratio is 0.33, hepatic clearance ($\mathrm{CL_H}$) equals 0.5 L/min. Total clearance is computed by summing all the individual organ clearance values. While many organs have the capability to clear drugs, the liver is the site of the vast majority of drug metabolism; therefore, the clearance provided by the liver is especially important and will be tahe focus of this section.

Clearance is altered when either the blood flow to extracting organs or the extraction ratio changes. Vasodilators such as hydralazine and nifedipine increase liver blood flow, whereas heart failure (HF) and hypotension can decrease hepatic blood flow. Extraction ratios can increase when enzyme inducers increase the amount of drug-metabolizing enzyme, whereas extraction ratios may decrease if necrosis causes loss of hepatic parenchyma. An understanding of these variables can help the clinician predict the impact on the clearance and, ultimately, the C_{ss} of the drug when changes occur.

The extraction ratio cannot be directly measured because of the inability to clinically measure concentrations of drug coming into and out of the liver. Therefore, an estimation of the extraction ratio must be made. One method of estimating the extraction ratio is through the well-stirred model, which assumes that the liver represents one well-stirred compartment. This model can estimate the extraction ratio by accounting for the unbound fraction of drug in the blood (f_u), the intrinsic ability of the extracting organ to clear unbound drug from the blood ($\mathrm{CL_{int}}$), and blood flow to the organ (Q).[7,8] Mathematically, this can be described as follows:

$$E = \frac{f_u(\mathrm{CL_{int}})}{Q + f_u(\mathrm{CL_{int}})}$$

E = fu(CLint)Q+fu(CLint)

Extraction ratio can thus be affected by any of these variables. Intrinsic clearance, which refers to the liver's maximum capacity to metabolize the drug in normal conditions (ie, enzymatic activity), is especially important. Drugs that have high intrinsic clearance usually have high extraction ratios, as drugs with low extraction ratios usually have low extraction ratios.

By substituting this equation for E in the formula $\mathrm{CL_H} = QE$, the clearance equation becomes

$$\mathrm{CL_H} = \frac{Q[f_u(\mathrm{CL_{int}})]}{Q + f_u(\mathrm{CL_{int}})}$$

CLH = Q[fu(CLint)]Q+fu(CLint)

Understanding the variables in this equation is important for predicting how the clearance of the drug will be altered when either the blood flow to the liver (Q), fraction of unbound drug (f_u), or enzymatic activity ($\mathrm{CL_{int}}$) change. Binding in the blood can change if the concentration of binding proteins is low (as in hypoalbuminemia due to malnutrition, for example) or if highly protein-bound drugs are displaced by a drug interaction. Intrinsic clearance is affected when the maximal enzymatic activity changes, such as when metabolizing enzymes are induced or inhibited by other pharmacotherapy or functional organ tissue is destroyed by disease processes such as cirrhosis. Depending on the properties of the drug, a clinician can use the well-stirred model to predict the clearance and C_{ss} following changes in any of these parameters.

Drugs such as propranolol, verapamil, and morphine have high intrinsic clearance, meaning that the liver is very effective at metabolizing the drug. This leads to a high extraction ratio—a large proportion of the drug that enters the liver is metabolized. If $\mathrm{CL_{int}}$ is large (enzymes have a high capacity to metabolize the drug), the product of f_u and CL_{int} is much larger than Q. When f_u (CL_{int}) is much greater than Q, the sum of Q and $f_u(CL_{int})$ in the denominator of the clearance equation almost equals f_u (CL_{int}):

$$f_u(CL_{int}) \approx Q + f_u(CL_{int})$$
fu(CLint)≈Q+fu(CLint)

Substituting this expression in the denominator of the clearance equation and canceling common terms leads to the following expression for drugs with a large CL_{int}:

$$CL_H \approx Q$$
CLH ≈ Q

In this case, clearance of the drug is equal to blood flow to the organ; such drugs are called high-clearance drugs and have large extraction ratios. This results in clearance being highly affected by the blood flow to the liver. In disease states such as cardiogenic shock, in which blood flow to the liver may be reduced, clearance will also be reduced.

Because they have high extraction ratios, these drugs often exhibit what is called a first-pass effect when administered orally. When drugs are given enterally, they are absorbed into the blood and pass through the liver prior to entering systemic circulation. If a large amount of the drug is extracted prior to reaching systemic circulation, the overall bioavailability of the drug is reduced. In order to reach desired concentrations systemically, larger doses are needed as compared to the IV formulations.

Conversely, drugs such as warfarin, diazepam, and phenobarbital have low extraction ratios. When CL_{int} is small (enzymes have a limited capacity to metabolize the drug), Q is much larger than the product of f_u and CL_{int}. When Q is much greater than $f_u(CL_{int})$, the sum of Q and $f_u(CL_{int})$ in the denominator of the clearance equation becomes almost equal to Q:

$$Q \approx Q + f_u(CL_{int})$$
Q≈Q+fu(CLint)

Substituting this expression in the denominator of the clearance equation and canceling common terms leads to the following expression for drugs with a small CL_{int}:

$$CL \approx f_u(CL_{int})$$
CL≈fu(CLint)

In this case, clearance of the drug is equal to the product of the fraction unbound in the blood and the intrinsic ability of the organ to clear unbound drug from the blood; such drugs are known as low-clearance drugs and have small extraction ratios. Because the liver is poorly able to metabolize the drug, the clearance is less affected by change in blood flow and is instead much more affected by unbound drug concentration and the intrinsic clearance. For example, if given with an enzyme inducer, the clearance of a low extraction ratio drug would increase and could cause below expected serum concentrations.

As mentioned previously, the concentration of unbound drug in the blood is more important pharmacologically than the total (bound plus unbound) concentration. The unbound drug in the blood is in equilibrium with the unbound drug in the tissues and reflects the concentration of drug at its site of action. Therefore, the pharmacologic effect of a drug is typically most closely associated with the concentration of unbound drug in the blood. The unbound steady-state concentration ($C_{ss,u}$) can be calculated by multiplying C_{ss} and f_u: $C_{ss,u} = C_{ss}\, f_u$. The effect that changes in Q, f_u, and CL_{int} have on $C_{ss,u}$ and therefore on the pharmacologic response of a drug depends on whether a high- or low-clearance drug is involved.

Because $CL_H = Q$ for high-clearance drugs, a change in f_u or CL_{int} does not change CL_H or C_{ss} (ie, $C_{ss} = R_0/CL$). However, a change in unbound drug fraction does alter $C_{ss,u}$ (ie, $C_{ss,u} = f_u C_{ss}$), thereby affecting the pharmacologic response. Plasma protein-binding displacement drug interactions can be very important clinically, but they are also dangerous because the changes in $C_{ss,u}$ are not reflected in changes in C_{ss} for high-clearance drugs. Because laboratories usually measure only total concentrations (concentrations of unbound drug are difficult to determine), the interaction is hard to detect. If CL_{int} changes for high-clearance drugs, CL_H, C_{ss}, $C_{ss,u}$, and pharmacologic response do not change. Changes in Q cause a change in CL_H; changes in C_{ss}, $C_{ss,u,}$ and drug response are indirectly proportional to changes in CL_H.

For low-clearance drugs, total clearance is determined by unbound drug fraction and intrinsic clearance: $CL_H = f_u(CL_{int})$. A change in Q does not change CL_H,C_{ss}, $C_{ss,u,}$ or pharmacologic response. However, a change in f_u or CL_{int} does alter CL and C_{ss} (ie, $C_{ss} = R_0/CL_H$). Changes in CL_{int} will cause a proportional change in CL_H. Changes in C_{ss}, $C_{ss,u,}$ and drug response are indirectly proportional to changes in CL_H. Altering f_u for low-clearance drugs produces interesting results. A change in f_u alters CL_H and C_{ss} (ie, $C_{ss} = R_0/CL_H$) but will not change the steady-state concentration of unbound drug (ie, $C_{ss,u} = f_u C_{ss}$). By substituting the C_{ss} formula in the equation for $C_{ss,u}$

$$C_{ss,u} = f_u \cdot \frac{R_0}{f_u \cdot CL_{int}}$$

Css,u = fu · R0fu · CLint

After canceling common terms, the equation becomes

$$C_{ss,u} = \frac{R_0}{CL_{int}}$$

Css,u = R0CLint

Thus, the $C_{ss,u}$ is related to only the rate of infusion and intrinsic clearance. Therefore, changes in f_u will alter total concentration, but no change in drug dosing is warranted since $C_{ss,u}$ is not expected to be altered by change in protein binding for a low extraction ratio drug.

Suppose that another drug is administered to the patient that displaces the first drug from plasma-protein-binding sites and doubles f_u (f_u now equals $2f_u$). CL_H doubles because of the protein-binding displacement ($2CL = 2f_u[CL_{int}]$), and C_{ss} decreases by one-half because of the change in clearance ($½[C_{ss}] = R_0/[2Cl]$). $C_{ss,u}$ does not change because even though f_u is doubled, C_{ss} decreased by one-half ($C_{ss,u} = f_u C_{ss}$). The potential for error in this situation is that clinicians may increase the dose of a low-clearance drug after a protein-binding displacement interaction because C_{ss} decreased. Because $C_{ss,u}$ and the pharmacologic effect do not change, the dose should remain unaltered. Plasma protein binding decreases occur commonly in patients taking phenytoin. Low albumin concentrations (as in patients who have experienced trauma or are pregnant), high concentrations of endogenous plasma protein-binding displacers (as with high concentrations of bilirubin), or plasma protein–binding drug interactions (as with concomitant therapy with valproic acid) can result in subtherapeutic total phenytoin concentrations. Despite this fact, unbound phenytoin concentrations usually are within the therapeutic range, and often the patient is responding appropriately to treatment. Thus, in these situations, unbound rather than total phenytoin serum concentrations should be monitored and used to guide future therapeutic decisions.

Clearances for individual organs can be computed if the excretion the organ produces can be obtained. For example, renal clearance can be calculated if urine is collected during a pharmacokinetic experiment. The patient empties his or her bladder immediately before the dose is given. Subsequent urine production is collected until the last serum concentration (C_{last}) is obtained. Renal clearance (CL_R) is computed by dividing the amount of drug excreted in the urine by $AUC_{0–t,last}$. Biliary and other clearance values are computed in a similar fashion.

Linear Pharmacokinetics

⑥ Most drugs follow linear pharmacokinetics, in which serum drug concentrations change proportionally with changes in dose over the clinically administered drug dosing range (Fig. e6-3). For example, if a drug dose were doubled from 300 mg to 600 mg daily, the expected serum concentration would double. Drugs exhibit linear pharmacokinetics when they are dosed over a range of concentrations that does not saturate the enzymes or transporters responsible for their elimination or the proteins or tissues to which they are bound. In other words, the elimination rate for the drug increases proportionately with increases in concentration. This occurs physiologically because as the concentrations increase, the pathways of enzymatic or non-enzymatic elimination can also increase, thereby, proportionately increasing the elimination rate. The elimination rate is the change in concentration per change in time and represents the rate at which the drug can be removed from the bloodstream.

$$\frac{\Delta C}{\Delta t} = -kC$$

ΔCΔt = −kC

FIGURE e6-3

Relationship of dose and steady-state drug concentration (C_{ss}) or area under the concentration-versus-time curve (AUC) under linear and nonlinear conditions.

Where $\Delta C/\Delta t$ is the change in the concentration per change in time (ie, the elimination rate), C is the plasma concentration, and k is the elimination rate constant. For drugs with first-order, non-saturable (linear) pharmacokinetics, the increases in plasma concentration produce a proportionate increase in the elimination rate over the dosing range of that drug. Consequently, the AUC of drugs that exhibit linear pharmacokinetics also increases proportionally with increase in dose.

Nonlinear Pharmacokinetics

⑦ Some drugs do not follow the rules of linear pharmacokinetics, which leads to a variety of nonlinear pharmacokinetic profiles. Instead of concentration changing proportionally with dose, serum concentrations change more or less than expected (Fig. e6-3).

Drugs exhibit nonlinear pharmacokinetics when their dosing range produces systemic concentrations that saturate the enzymes responsible for their elimination (Michael-Menten) or binding proteins (nonlinear protein binding), induce their own metabolism (autoinduction), or bind extremely tightly to their receptor target (target-mediated drug distribution). For example, if a drug is required to be dosed at concentrations that saturate the drug metabolizing enzymes responsible for the drug's elimination, then the elimination rate will no longer be able to increase in proportion with increases in drug dose or concentration. Therefore, as concentration rate increases, elimination rate ($\Delta C/\Delta t$) will not change and become a flat, constant rate of elimination (zero order). In this example, the concentrations will now increase disproportionately with an increase in dose. This is particularly clinically relevant because a doubling in dose would produce a more than doubling of the plasma concentration, which could put the patient are risk of toxicity if the concentrations achieved are outside of the therapeutic range. Nonlinear protein binding can cause the reverse—an increase in f_u will lead to increased CL for low clearance drugs. An increase in dose would then result in a less than anticipated serum concentration, which may fail to reach the intended therapeutic range and/or produce the desired effect of the medication.

Phenytoin is an anti-seizure medication that is well known to have nonlinear pharmacokinetics.[9] The doses of phenytoin commonly administered can produce plasma concentrations that saturate the enzymes responsible for its elimination. It is important that pharmacists recognize drugs like phenytoin with nonlinear pharmacokinetics so that dose changes are not incorrectly assumed to produce equal changes in systemic concentration. Drugs with nonlinear pharmacokinetics should be adjusted cautiously and monitored closely, often with plasma drug concentrations, to ensure both safe and effective dosing.

Half-Life

⑧ The pharmacokinetic parameter that describes the time required for serum concentrations to decrease by one-half is half-life. Half-life is dependent on the values of clearance and volume of distribution. It takes the same amount of time for serum concentrations to drop from 200 to 100 mg/L as it does for concentrations to decline from 2 to 1 mg/L (Fig. e6-4) due to concentration-dependent elimination. Charted on logarithmic graph paper, the elimination rate constant can be described as the slope of the serum concentration ($-k/2.303$), though this is often changed to a natural log (ln) for presentation purposes, with the slope then equal to $-k$. For the remainder of this chapter, formulas will be presented using natural log. The $t_{1/2}$ can then be calculated using the equation:

$t_{½} = \frac{\ln 2}{k} = \frac{0.693}{k}$t½ = ln 2k = 0.693k

FIGURE e6-4

Calculation of the half-life of a drug following IV bolus dosing.

Half-life is a dependent kinetic variable because its value depends on the values of CL and V_D.[5] The equation that describes the relationship among the three variables is $t_{1/2} = 0.693\ V_D/\text{CL}$. Changes in $t_{1/2}$ can result from a change in either V_D or CL; a change in $t_{1/2}$ does only occur when CL has changed. Half-life can also change solely because of changes in V_D. The elimination rate constant (k) is related to the half- life by the following equation: $k = 0.693/t_{1/2}$. Both the half-life and elimination rate constant describe how quickly serum concentrations decrease in the serum or blood.

Half-life is important because it determines the time required to reach steady state, the time to complete drug elimination, and the dosage interval. It takes approximately three to five half-lives to reach steady-state concentrations during continuous dosing. In 3 to 5 half-lives, serum concentrations are at ~90% and 96.9% of their ultimate steady-state values, respectively. Because most serum drug assays have an ~10% error, it is difficult to differentiate concentrations that are within 10% of each other. For this reason, many clinicians consider concentrations obtained within the 3 to 5 half-live range to be C_{SS}.

Half-life is also used to determine the dosage interval for a drug (τ). For example, it may be desirable to maintain peak or maximal steady-state concentrations at 20 mg/L and minimum or trough steady-state concentrations at 10 mg/L. In this case, it would be necessary to administer the drug every half-life because the minimum desirable concentration is one-half the maximum desirable concentration.

Linear Pharmacokinetic Concepts

⑨ Pharmacokinetic models are useful to describe data sets, to predict serum concentrations after several doses or different routes of administration, and to calculate pharmacokinetic constants such as clearance, volume of distribution, and half-life.[10] Figure e6-1 contains examples of different administration methods and distributions that follow linear pharmacokinetics.

Compartmental models depict the body as one or more discrete compartments to which a drug is distributed and/or from which a drug is eliminated. The shape of the serum-concentration-versus-time curve determines the number of compartments in the pharmacokinetic model and the equation used in computations (Fig. e6-1). For clinical dosage adjustment purposes using drug concentrations, a one-compartment model is the most commonly used pharmacokinetic model.

IV Bolus, One Compartment

After an IV bolus in a one compartment linear model, the concentration of the drug will decrease in exponential fashion when plotted on graph paper (Fig e6-1); however, using semilogarithmic coordinates, serum concentrations decline in a straight line. The slope of the line is $-k/2.303$; when using a natural log scale, this means slope is $-k$. Once k is known, the $t_{1/2}$ can be computed by determining the time required for concentrations to decrease by one-half ($t_{1/2} = 0.693/k$) (see Fig. e6-4). The equation that describes the concentration (C_t) at a given time (t) is as follows:

$$C_t = C_0 e^{-kt}$$
Ct = C0e−kt

The y-intercept is the concentration at time zero (C_0), which can also be described as follows:

$$C_0 = \frac{dose}{V_D}$$
C0 = doseVD

When substituting this equation for C_0, the resulting equation can be used to compute concentration at any time after the dose once V_D and are known:

$$C_t = \frac{\text{dose}}{V_D} e^{-kt}$$
Ct = doseVDe−kt

If the drug is given at intermittent dosage intervals, such as 250 mg every 6 hours, steady state is achieved when the serum-concentration-versus-time curves for each dosage interval are superimposable. The amount of drug eliminated during the dosage interval equals the dose.

IV Bolus, Two Compartment

After an IV bolus dose, serum concentrations often decline in two or more phases (see Fig e6-1). During the early phases, the drug leaves the bloodstream by two mechanisms: (1) distribution into tissues and (2) metabolism and/or elimination. Both the distribution and elimination processes are often first order, concentration-dependent rate processes; therefore, at early time points after an IV bolus when concentrations are high, these serum concentrations will decline rapidly. First-order rate constants, known as microconstants, describe the rate of transfer from one compartment to another. Each compartment also has its own V_D. After tissues and blood are in equilibrium, only metabolism and elimination remove the drug from the blood. During this terminal phase, serum concentrations decline more slowly. The half-life is measured during the terminal phase by determining the time required for concentrations to decline by one-half.

The two-compartment model is encountered most commonly (see Fig. e6-5). After an IV bolus injection, serum concentrations decrease in two distinct phases, described by the equation:

$$C_t = \frac{D(\alpha - k_{21})}{V_{D1}(\alpha - \beta)} e^{-\alpha t} + \frac{D(k_{21} - \beta)}{V_{D1}(\alpha - \beta)} e^{-\beta t}$$
Ct=D(α−k21)VD1(α−β)e−αt+D(k21−β)VD1(α−β)e−βt

or $C_t = Ae^{-\alpha t} + Be^{-\beta t}$, where k_{21} is the first-order rate constant that reflects the transfer of the drug from compartment 2 to compartment 1, V_{D1} is the V_D of compartment 1, $A = D(\alpha - k_{21})/(V_{D1}[\alpha - \beta])$ and $B = D(k_{21} - \beta)/(V_{D1}[\alpha -])$. The rate constants α and found in the exponents of the equations describe the distribution and elimination of the drug, respectively (Fig. e6-6). A and B are the y intercepts of the lines that describe drug distribution and elimination, respectively, on the concentration-versus-time plot.

The residual line is calculated as before using the method of residuals (see Fig. e6-6, inset). The terminal line is extrapolated to the *y* axis, and extrapolated concentrations are determined for each time point. Because actual concentrations are greater in this case, residual concentrations are calculated by subtracting the extrapolated concentrations from the actual concentrations, where

$$\mathit{Actual}: C_t = Ae^{-\alpha t} + Be^{-\beta t}$$
Actual: Ct = Ae−αt+Be−βt
$$\mathit{Extrapolated}: C_{ext,t} = Be^{-\beta t}$$
Extrapolated: Cext,t = Be−βt
$$\mathit{Residual}: C_{res,t} = Ae^{-\alpha t}$$
Residual: Cres,t = Ae−αt

When using a natural log scale, the residual line has a *y* intercept equal to *A*. The slope of the residual line is used to compute *α* (slope = −*α*). With the rate constants (α and β) and the intercepts (A and B), concentrations can be calculated for any time after the IV bolus dose ($C_t = Ae^{-\alpha t} + Be^{-\beta t}$), or pharmacokinetic constants can be computed:

$$\mathrm{AUC}_0^\infty = \frac{A}{\alpha} + \frac{B}{\beta}$$
AUC0∞=Aα+Bβ
$$\mathrm{CL} = \frac{\mathrm{dose}}{\mathrm{AUC}_0^\infty}$$
CL=doseAUC0∞

In multicompartment models, multiple V_D parameters are needed to accurately describe the data. $V_{D,\beta}$ describes the volume of distribution after the distribution phase, and $V_{D,ss}$ describes the sum of the volumes of the compartments when at equilibrium. In order to calculate $V_{D,ss}$, an area under the moment (AUMC) curve is used, in which the product of the concentration and time is plotted by time.

$$V_{\mathrm{D},\beta} = \frac{\mathrm{dose}}{\mathrm{AUC}_0^\infty \cdot \beta}$$
VD,β=doseAUC0∞ · β
$$V_{\mathrm{D,ss}} = \frac{\mathrm{dose} \cdot \mathrm{AUMC}}{\mathrm{AUC}^2}$$
VD,ss=dose · AUMCAUC2

Continuous IV Infusion

During a continuous IV infusion, the serum concentrations in a one-compartment model change according to the following function:

$C_t = \frac{R_0}{\mathrm{CL}}\left(1 - e^{-kt}\right)$ Ct=R0CL(1−e−kt)

Serum concentrations increase until an equilibrium is established between the drug dosage rate and the rate of drug elimination. As time increases and approaches steady state at 3 to 5 half-lives, the (1-e^{kt}) function approaches a value of 1. At that point, the rate of drug administration equals the rate of drug elimination, and the serum concentrations remain constant (Fig. e6-1). CL can then be calculated (CL =R_0/C_{ss}). When the infusion is discontinued, serum concentrations decline in a straight line on the natural log scale with a slope of −*k*. V_D is computed by dividing CL by *k* (Fig. e6-7).

FIGURE e6-7

Achievement of steady-state serum concentrations after 3 to 5 half-lives of a drug. Note the elimination phase after discontinuance of the infusion.

For example, if a patient were receiving a continuous IV infusion of theophylline at 40 mg/hr, the theophylline serum concentration would increase until the patient's body was eliminating theophylline at 40 mg/hr. When serum drug concentrations reach a constant value, steady state is achieved.

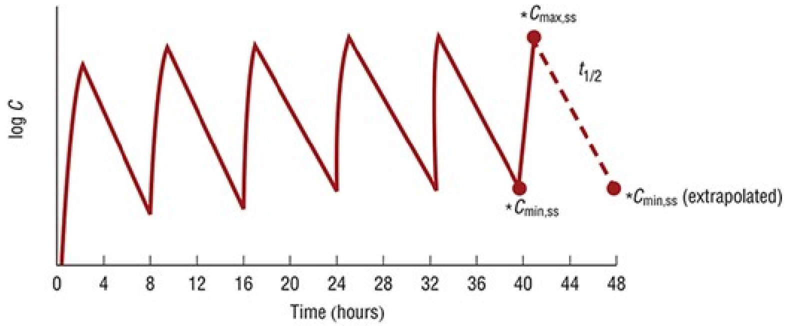
Multiple Dosing and Steady-State Equations

Any of these compartmental equations can be used to determine serum concentrations after multiple doses (Fig. e6-8). The multiple-dosing factor $(1 - e^{-kK\tau})/(1 - e^{-k\tau})$ where *n* is the number of doses, *k* is the appropriate rate constant, and *τ* is the dosage interval is simply multiplied by each exponential term in the equation, substituting the rate constant of each exponent for *k*. Time (*t*) is set at 0 at the beginning of each dosage interval. For example, a single-dose two-compartment IV bolus is calculated as follows: $C_t = Ae^{-\alpha t} + Be^{-\beta t}$. Thus, the equation for a multiple-dose two-compartment IV bolus is

$$C_t = Ae^{-\alpha t}\frac{1-e^{-n\alpha\tau}}{1-e^{-\alpha\tau}} + Be^{-\beta t}\frac{1-e^{-n\beta\tau}}{1-e^{-\beta\tau}}$$
Ct=Ae−αt1−e−nατ1−e−ατ+Be−βt1−e−nβτ1−e−βτ

FIGURE e6-8

When a patient has received enough doses to be at steady state, steady-state maximum ($C_{\max,ss}$) and minimum ($C_{\min,ss}$) concentrations can be used to compute clearance, volume of distribution, and half-life. At steady state, consecutive $C_{\min,ss}$ values are equal, so the predose value can be extrapolated to the time before the next dose and used to calculate the half-life (dashed line).



Source: Joseph T. DiPiro, Gary C. Yee, L. Michael Posey, Stuart T. Haines, Thomas D. Nolin, Vicki L. Ellingrod: *DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e*
Copyright © McGraw Hill. All rights reserved.

A single-dose one-compartment IV bolus is calculated as $C_t = (D/V_D)e^{-kt}$. For a multiple-dose one-compartment IV bolus, the concentration is C:

$$C_t = \left(\frac{D}{V_D}\right)e^{-kt} \times \frac{1-e^{-nk\tau}}{1-e^{-k\tau}}$$
Ct=(DVD) e−kt × 1−e−nkτ1−e−kτ

At steady state, the number of doses becomes large, $e^{-nk\tau}$ approaches zero, and the multiple-dosing factor equals $1/(1 - e^{-k\tau})$. Therefore, the steady-state versions of the equations are simpler than their multiple-dose counterparts:

$$C_t = Ae^{-\alpha t}\frac{1}{1-e^{-\alpha\tau}} + Be^{-\beta t}\frac{1}{1-e^{-\beta\tau}}$$
Ct=Ae−αt11−e−ατ+Be−βt11−e−βτ

and

$$C_t = C_0e^{-kt} \times \frac{1}{1-e^{-k\tau}}$$
Ct=C0e−kt×11−e−kτ

for a steady-state two-compartment IV bolus and a steady-state one-compartment IV bolus, respectively.

Extravascular Administration

When drugs are administered extravascularly, drug molecules must be released from the dosage form (dissolution) and pass through several biologic barriers before reaching the vascular system (absorption). The fraction of drug absorbed into the systemic circulation (*F*) after extravascular administration is defined as its bioavailability and can be calculated after single IV and extravascular doses as[11]

$$F = \frac{D_{iv} * \mathrm{AUC}_0^\infty}{D * \mathrm{AUC}_{iv_0}^\infty}$$
F=Div∗AUC0∞D∗AUCiv0∞

where D and D_{iv} are the extravascular and IV doses, respectively, and $\mathrm{AUC}_{iv,0\text{-}\infty}$ and $\mathrm{AUC}_{0\text{-}\infty}$ are the IV and extravascular areas under the serum- or blood-concentration-versus-time curves, respectively, from time zero to infinity. (Fig. e6-2). When is less than 1 for a drug administered extravascularly, either the dosage form did not release all the drug contained in it, or some of the drug was eliminated or destroyed (by stomach acid or other means) before it reached the systemic circulation.

When the extravascular dose is administered orally, part of the dose may be metabolized by enzymes or removed by transport proteins contained in the GI tract wall or liver before it reaches the systemic circulation.[12,13] This occurs commonly when drugs have a high liver extraction ratio or are subject to GI tract wall metabolism because, after oral administration, the drug must pass through the GI tract wall and into the portal circulation of the liver. This removal/metabolism of the parent drug by the liver prior to reaching the circulation is known as the "first-pass effect." This is so named because the drug must first pass the liver before reaching systemic circulation. For example, if an orally administered drug is 100% absorbed from the GI tract but has a hepatic extraction ratio of 0.75, only 25% of the original dose enters the systemic circulation. Transport proteins are also present in the GI tract wall that can actively pump drug molecules that already have been absorbed back into the lumen of the GI tract. P-glycoprotein (P-gp) is the primary transport protein that interferes with drug absorption by this mechanism. This first-pass effect through the liver and/or GI tract wall is avoided when the drug is given by other routes of administration. The computation of F does not separate loss of oral drug metabolized by the first-pass effect and drug not absorbed by the GI tract. Special techniques are needed to determine the fraction of drug absorbed orally for drugs with high liver extraction ratios and/or substantial gut wall metabolism.

When an extravascular dose is given, one-compartment-model serum concentrations rise during absorption, then decrease in a straight line with a slope equal to $-k$. The equation that describes the data is shown below, where F is the fraction of the dose absorbed into the systemic circulation. The absorption rate constant (k_a) is obtained using the method of residuals.

The method of residuals is used to obtain the individual rate constants (Fig. e6-9). A is determined by extrapolating the terminal slope to the y axis; k can be obtained by calculating the slope or $t_{1/2}$ and using the formulas given for the IV bolus case. At each time point in the absorption portion of the curve, the concentration value from the extrapolated line is noted and called the extrapolated concentration. For each point, the actual concentration is subtracted from the extrapolated concentration to compute the residual concentration. When the residual concentrations are plotted on semilogarithmic coordinates (see Fig. e6-9, inset), a line with y intercept equal to A and slope equal to $-k_a/2.303$ is obtained. When these values are calculated, they can be placed into the equation:

$$C = Ae^{-kt} - Ae^{-kat}$$
C=Ae−kt−Ae−kat

where $A = \frac{FDk_a}{V_D(k_a - k)}$ A=FDkaVD(ka−k) and used to compute the serum concentration at any time after the extravascular dose. The intercepts and rate constants also can be used to compute CL and V_D:

$$\mathrm{CL} = \frac{\mathrm{FD}}{\left({}^{A}\!/_{k} - {}^{A}\!/_{k_a}\right)} \text{ and } V_D = {}^{\mathrm{CL}}\!/_{k}$$
CL=FD(Ak−Aka) and VD=CLk

where F is the fraction of the dose absorbed into the systemic circulation.

Two different dosage forms of the same drug are considered to be bioequivalent when the $\mathrm{AUC}_{0-\infty}$, maximum serum or blood concentrations ($C_{\max}$), and the times that $C_{\max}$ occurs ($t_{\max}$) are neither clinically nor statistically different. When this occurs, the serum-concentration-versus-time curves for the two dosage forms should be superimposable and identical. Bioequivalence studies have become very important as expensive drugs become available in less costly generic form. Most bioequivalence studies involve 18 to 25 healthy adults who are given the brand-name product and the generic product in a randomized, crossover study design in order to statistically compare the two formulations' pharmacokinetic profiles.

Usually, the elimination is the rate limiting step in the drug's pharmacokinetic profile (ie, $k >>> k_a$). However, some oral drugs are prolonged or delayed absorption so that the half-life appears much longer when administered enterally than when given IV. This means that the rate-limiting step is the absorption instead of the elimination (ie, $k_a >>> k$), which leads to "flip flop kinetics." In this case, the slope does not solely represent the elimination process. This may be a coincidental finding, as with acamprosate, or may be a result of sustained release formulation. In these cases, the k_a is important for determining the $t_{½}$ of the drug.[14] Many sustained release products take advantage of slow gastrointestinal transit time to prolong k_a and thus, prolong the $t_{½}$ of the drug.

Nonlinear Pharmacokinetic Concepts

Michaelis-Menten Kinetics

Some drugs do not follow the rules of linear pharmacokinetics. Instead of C_{ss} and AUC increasing proportionally with dose, serum concentrations change more or less than expected (Fig. e6-3). One explanation for the greater-than-expected increase in C_{ss} and AUC after an increase in dose is that the enzymes responsible for the metabolism or elimination of the drug may start to become saturated. When this occurs, the maximum rate of metabolism (V_{max}) for the drug is approached when drug concentrations are high. This is called Michaelis-Menten kinetics. The potency of a given drug is determined by the serum concentration at which the rate of metabolism equals $V_{max}/2$, which is known as the K_m. Practically speaking, K_m is the serum concentration above which nonproportional changes in C_{ss} and AUC start to occur when the dose is increased. The Michaelis-Menten constants (V_{max} and K_m) determine the maintenance dose (mg/day) needed to maintain a given C_{ss}:

$$\text{Maintenance dose} = \frac{V_{max} C_{ss}}{(K_m + C_{ss})}$$

Maintenance dose=VmaxCss(Km+Css)

Most drugs eliminated by the liver are metabolized by enzymes but still follow linear kinetics. The reason for this disparity is that the therapeutic range for most drugs is well below the K_m of the enzyme system that metabolizes the agent. The therapeutic range is higher than K_m for some commonly used drugs; however, some drugs are dosed at ranges that are well above the K_m to reach therapeutic concentrations. One example is the antiseizure medication phenytoin. For example, the average K_m for phenytoin is about 5 to 6 mg/L (mcg/mL; 20-24 µmol/L).[15] The therapeutic range for phenytoin is usually 10 to 20 mg/L (mcg/mL; 40-79 µmol/L). Thus, most patients experience saturable Michaelis-Menten kinetics while taking phenytoin and changes in dosing must be cautiously optimized.

Nonlinear Protein Binding

Typical Nonlinear Protein Binding

Another type of nonlinear kinetics can occur if C_{ss} and AUC increase less than expected after an increase in dose of a low-clearance drug. This usually indicates that plasma protein-binding sites are starting to become saturated, so that f_u increases with increases in the dose (Fig. e6-3). For a low-clearance drug, CL depends on the values of f_u and CL_{int} ($CL = f_u CL_{int}$). When a dosage increase takes place, f_u increases because nearly all plasma protein-binding sites are occupied, and no binding sites are available. If f_u increases, CL increases, and C_{ss} increases less than expected with the dosage change ($C_{ss} = R_0/\text{CL}$). However, $C_{ss,u}$ increases proportionally with the dose because $C_{ss,u}$ depends on CL_{int} for low-clearance drugs ($C_{ss,u} = R_0/\text{CL}_{int}$). Clinically, the increased f_u will result in increased total concentration but no change in free concentration; thereby, an observed increase in total concentration would not warrant a change in dose since free drug in responsible for the effect. Valproic acid is an example of a commonly used drug that follows saturable protein-binding pharmacokinetics.[9,15,16]

Atypical Nonlinear Protein Binding

Some drugs may also display an atypical nonlinear protein binding, in which the fraction of unbound drug is not linear but does not follow the saturation model as above.[17,18] The most common is the reverse of typical protein binding—the fraction of unbound drug decreases with increasing plasma concentrations. Several of the tetracyclines, including doxycycline and eravacycline, display this effect. Even more complex, some drugs, such as tigecycline, seems to have a U-shaped relationship between serum concentration and free fraction. In both of these instances, increasing doses may achieve lower than expected concentrations of free drug and fail to produce the desired clinical effect. Drugs that display these effects require complex modeling to describe their pharmacokinetics.[17,18]

Autoinduction

For some drugs, clearance increases as the dose or concentration of the drug increases. In this situation, increasing the drug dose or concentration increases the ability of the enzyme system to eliminate the compound and to clear the drug from the body. This is usually accomplished by inducing the enzyme system responsible for the metabolism of the drug, so that the intrinsic clearance of the drug increases. Because the drug itself is causing an increase in its own metabolism, this process is called autoinduction. For some drugs, such as carbamazepine,[9,15] the autoinduction effect is continuous within the typical dosage range, which produces a curve for the dose versus C_{ss} or AUC plot similar to nonlinear protein binding (Fig. e6-3). Detailed pharmacokinetic studies are conducted to differentiate between nonlinear protein binding and autoinduction when dose versus C_{ss} or AUC plots systematically deviate below the linear line.

Target-Mediated Drug Disposition

Nonlinear pharmacokinetics are often seen in both large molecule drugs, such as monoclonal antibodies (eg, denosumab) or recombinant proteins (eg, filgrastim), and in some small molecule drugs, such as linagliptin, a commonly used medication to treat type 2 diabetes mellitus.[19–21] This phenomenon is a result of a pharmacodynamic process (high-affinity binding of the drug to its receptor target) affecting the pharmacokinetics of the drug, which is called target-mediated drug disposition.[21] While target-mediated drug disposition was first described in the 1990s, the rapid increase in large molecule drugs that fit the pharmacokinetic pattern has increased substantially. A number of factors are needed to result in target-mediated drug disposition: the drug must have high binding affinity to its receptor, the binding must be specific (ie, the drug binds with high affinity only to its target, not to other proteins or tissues), and the capacity for binding must be low, which means the process can be easily saturated.[19] When a single, low dose is given, most of the drug binds to its intended target and little is left remaining in systemic circulation. Because the capacity for binding the drug is low, when doses are increased, there are not as many available binding sites for the drug. As such, increasing amounts of the drug will remain in systemic circulation and the serum concentration will increase more than would be expected with linear pharmacokinetics. After all sites are saturated (typically at high doses), the serum concentration will usually increase linearly. The increasing emergence of large molecule and immunotherapeutic novel drug therapies is increasing the importance of understanding nonlinear pharmacokinetic processes as they relate to patient drug dosing.

Use of Pharmacokinetic Concepts for Individualization of Pharmacotherapy

⑩ Many factors should be taken into consideration when deciding on the best drug dose for a patient. These include patient-specific factors, including age, sex, weight, race/ethnic background, genetics, other concurrent disease states, kidney function, and hepatic function, as well as drug-specific factors (drug-drug interactions, drug-food interactions).

Patient-Specific Factors

The age of the patient is important because developmental stage and aging may result in alterations in drug absorption, distribution, and/or elimination.[22,23] For example, the dose (in milligrams per kilogram) for pediatric patients may be higher and for geriatric patients may be lower than the typically prescribed dose for young adults. Sex can also be a factor because male and female patients metabolize and eliminate some drugs differently. Patients who are significantly obese or cachectic also may require different drug doses because of clearance and volume of distribution changes. Disease states and conditions may alter the drug-dosage regimen for a patient. Three disease states that deserve special mention are heart failure, kidney disease, and hepatic disease. Kidney and hepatic diseases cause loss of organ function and decreased drug elimination and metabolism. Heart failure causes decreased blood flow to organs that clear the drug from the body. Coadministered pharmacotherapy that could cause drug interactions needs to be considered. Additionally, several enzymes responsible for drug metabolism have been found to exhibit significant genetic variations. These pharmacogenetic implications are discussed extensively in Chapter e7.

Drug-Specific Considerations

Many drug compounds are racemic mixtures of stereoisomers. In most cases, one of the isomers is more pharmacologically active than the other isomer, and each isomer may exhibit different pharmacokinetic properties. Warfarin, propranolol, verapamil, and ibuprofen are all racemic mixtures of stereoisomers. Some drug interactions inhibit or increase the elimination of only one stereoisomer. The importance of the drug interaction depends on which isomer is affected. Other drugs, such as dextromethorphan, levofloxacin, and diltiazem, are composed of just one stereoisomer. In some cases, drug development has focused on administration of a single isomer to improve drug therapeutic and pharmacokinetic variability. One such drug is escitalopram for the treatment of depression.

⑪ The cytochrome P450 family of enzymes is responsible for most drug metabolism oxidation reactions. Several cytochrome P450 (CYP) isozymes have been identified that are responsible for the metabolism of many important drugs (Table e6-2). CYP2C19 metabolizes most proton pump inhibitors, sertraline, and voriconazole; CYP1A2 is the enzyme that is responsible for the demethylation of caffeine and theophylline; CYP2C9 metabolizes phenytoin, losartan, and ibuprofen; CYP3A4 metabolizes some antiretroviral protease inhibitors, cyclosporine, and; and ethanol is a substrate for CYP2E1. It is important to recognize that a drug may be metabolized by more than one cytochrome P450 isozyme. Although most tricyclic antidepressants are hydroxylated by CYP2D6,N-demethylation probably is mediated by a combination of CYP2C19, CYP1A2, and CYP3A4. Acetaminophen metabolizes by both CYP1A2 and CYP2E1. The CYP3A enzyme family comprises ~90% of the drug-metabolizing enzyme present in the intestinal wall but only ~29% of the drug-metabolizing enzyme found in the liver. The remainder of hepatic drug-metabolizing enzyme is ~18% for the CYP2C family, ~13% for CYP1A2, ~7% for CYP2E1, and ~2% for CYP2D6.[24]

TABLE e6-2

Cytochrome P450 Enzyme Family and Selected Substrates

- CYP1A2
  - Acetaminophen
  - Caffeine
  - Ondansetron
  - Tacrine
  - Theophylline
  - *R*-warfarin
  - Zileuton
- CYP2C9
  - Candesartan
  - Diclofenac
  - Ibuprofen
  - Losartan
  - Naproxen
  - Phenytoin
  - Tolbutamide
  - Valsartan
  - *S*-warfarin
- CYP2C19
  - Diazepam
  - Lansoprazole
  - (S)-mephenytoin
  - Nelfinavir
  - Omeprazole
  - Pantoprazole
  - Voriconazole
- CYP2D6
  - Carvedilol
  - Codeine
  - Debrisoquine
  - Dextromethorphan
  - Encainide
  - Fluoxetine
  - Haloperidol
  - (S)-metoprolol
  - Paroxetine
  - Propafenone
  - Risperidone
  - Thioridazine
  - Venlafaxine
- CYP2E1
  - Enflurane
  - Ethanol
  - Halothane
  - Isoflurane
- CYP3A4
  - Alfentanil
  - Alprazolam
  - Astemizole
  - Carbamazepine
  - Cyclosporine
  - Diltiazem
  - Erythromycin
  - Felodipine
  - Itraconazole
  - Ketoconazole
  - Lidocaine
  - Lovastatin
  - Midazolam
  - Nifedipine
  - Quinidine
  - Simvastatin
  - Tacrolimus
  - Verapamil
  - Ziprasidone

Understanding which cytochrome P450 isozyme is responsible for the metabolism of a drug is extraordinarily useful in predicting and understanding drug interactions. Some drug-metabolism inhibitors and inducers are highly selective for certain CYP isozymes.[25] Clarithromycin is a strong inhibitor of the CYP3A4 enzyme system; when given with simvastatin, which is metabolized by CYP3A4, the hepatic clearance of the simvastatin is reduced, leading to increased risk of toxicity.[26] Ciprofloxacin and zileuton inhibit, whereas tobacco and marijuana smoke induce, CYP1A2. Some drugs that are enzyme inhibitors are also substrates for that same enzyme system and cause drug interactions by being a competitive inhibitor. For example, erythromycin is both a substrate for and an inhibitor of CYP3A4. Obviously, if one knows that a new drug is metabolized by a given CYP enzyme system, it is logical to assume that the new drug will exhibit drug interactions with the known inducers and inhibitors of that CYP isozyme.

⑫ Membrane transporters are protein molecules concerned with the active transport of drugs across cell membranes. Transport proteins are important in the processes of drug bioavailability, elimination, and distribution. The importance of membrane transport proteins is now better understood.[25,27,28] Membrane transporters are protein molecules concerned with the active transport of drugs across cell membranes. This results in the transfer of drug molecules either out of or into cells. Membrane transporters have been found in the intestine, liver, kidney, and the blood-brain barrier (Table e6-3).

TABLE e6-3

Membrane Transport Proteins and Selected Substrates

P-Glycoprotein (P-gp) *Sites: Intestinal enterocytes, kidney proximal tubule, hepatocytes (canalicular), brain endothelia* Alfentanil Aliskiren Ambrisentan Atorvastatin Azithromycin Cetirizine Citalopram Clopidogrel Cyclosporine Daunorubicin Dexamethasone Digoxin Diltiazem Doxorubicin Erythromycin Etoposide Fexofenadine Glyburide Indinavir Imatinib Loperamide Loratadine Lovastatin Morphine Nelfinavir Olanzapine Ondansetron Paclitaxel Quinidine Raltegravir Ranolazine Risperidone Rifampin Ritonavir Saquinavir Tacrolimus Telaprevir Verapamil Vinblastine Vincristine	OAT1B1 *Site: Hepatocytes (sinusoidal)* Bosentan Olmesartan Repaglinide Statins Valsartan OAT1 *Sites: Kidney proximal tubule, placenta* Acyclovir Cephradine Ciprofloxacin Methotrexate Zidovudine OAT3 *Sites: Kidney proximal tubule, choroid plexus, brain endothelia* Bumetanide Cefaclor Ceftizoxime Furosemide NSAIDs OCT1 *Sites: Hepatocytes (sinusoidal), intestinal enterocytes* Metformin Oxaliplatin OCT2 *Sites: Kidney proximal tubule, neurons* Amantadine Amiloride Metformin Pindolol Procainamide Ranitidine

OAT, organic anion transporter; OCT, organic cation transporter; NSAIDs, nonsteroidal anti-inflammatory drugs.

Data from Reference 4.

A principal transport protein involved in the movement of drugs across biologic membranes is P-gp. P-gp is present in many organs, including the GI tract, liver, and kidney. If a drug is a substrate for P-gp, its oral absorption may be decreased when P-gp transports drug molecules that have been absorbed back into the GI tract lumen. In the liver, some drugs are transported by P-gp from the blood into the bile, where the drug is eliminated by biliary secretion. Similarly, some drugs eliminated by the kidney are transported from the blood into the urine by P-gp. Digoxin is a substrate of P-gp. Other possible mechanisms for drug interactions are when two drugs that are substrates for P-gp compete for transport by the protein and when a drug is an inhibitor or inducer of P-gp. Drug interactions involving inhibition of P-gp decrease drug transportation in these organs and potentially can increase GI absorption of an orally administered drug, decrease biliary secretion of the drug, or decrease renal elimination of drug molecules. The drug interaction between amiodarone and digoxin probably involves all three of these mechanisms; this explains why digoxin concentrations increase so dramatically in patients receiving amiodarone. Many drugs that are metabolized by CYP3A4 are also substrates for P-gp, and some of the drug interactions attributed to inhibition of CYP3A4 may be a result of decreased drug transportation by P-gp. Drug interactions involving induction of P-gp have the opposite effect in these organs and may decrease GI absorption of an orally administered drug, increase biliary secretion of the drug, or increase renal elimination of drug molecules. Other membrane transporter families include the organic cation transporters (OCT family), organic anion transporters (OAT family), and the organic anion transporting polypeptides (OATP family).

Many CYP isozymes and transport proteins have been associated with genetic variations. CYP and other enzymes with more than one form of the give enzymatic functional protein are known as poly- (many) -morphic (form). Genetic differences will produce polymorphic variants of a given enzymatic protein in a population of patients with some patients inheriting a non-functional or poorly metabolizing variant of the enzyme. As a consequence, there are “poor metabolizers” who have a defective mutant gene for the isozyme, cannot manufacture a fully functional isozyme, and therefore cannot metabolize the drug substrate very well. “Extensive metabolizers” have the standard gene for the isozyme and metabolize the drugs normally. Occasionally, patients will inherit multiple highly functional copies of the same enzyme and are known as “ultrarapid metabolizers” based on their enhanced ability to metabolize drugs in comparison to the average individual. Poor and ultrarapid metabolizers usually are a minority of the general population. They may achieve supra- or sub-therapeutic concentrations, respectively, of a drug when usual doses are prescribed for them. If the active drug moiety is a metabolite, it may fail to have any pharmacologic effect from the drug in poor metabolizers or lead to toxicity in ultrarapid metabolizers. Detailed discussion of these concepts can be found in Chapter e7.

Kidney Function Considerations

⑬ When deciding on initial doses for drugs that are eliminated renally, the patient's kidney function should be assessed. A common, useful way to do this is to measure the patient's serum creatinine concentration and convert this value into an CL_{cr} or estimated glomerular filtration rate (eGFR). Serum creatinine values alone should not be used to assess kidney function because they do not include the effects of age, body weight, or sex. Methods for evaluating kidney function can be found in Chapter e60.

For drugs that are primarily excreted as unchanged drug in the urine, dose adjustments are usually required with declining kidney function due to a decrease in renal clearance. Many drugs have specific renal adjustments included in the FDA-approved labeling. For drugs that are eliminated primarily by the kidney but that do not have specific pharmacokinetic dosing guidelines, clinicians should consider adjustment of dose based on kidney function. In addition to a decrease in renal excretion, other pharmacokinetic parameters can also be altered by kidney disease. Detailed recommendations for adjusting doses in patients with chronic kidney disease are available in Chapter 67. When adjusting the dose for kidney function, careful consideration must be paid to the therapeutic index of the drug, alternate clearance pathways, patient-specific factors (eg, concurrent disease states), and the risk/benefit profile for the drug in question.

Liver Function Considerations

⑭ When deciding on initial doses for drugs that are hepatically eliminated, the patient's liver function should be assessed. The Child-Pugh score can be used as an indicator of a patient's ability to metabolize drugs that are eliminated by the liver. Unfortunately, there is no single test that can estimate liver drug-metabolism capacity accurately, and those that are used do not always prove accurate. High aminotransferase (aspartate aminotransferase [AST] and alanine aminotransferase [ALT]) and alkaline phosphatase concentrations usually indicate acute hepatic cellular damage and do not establish poor liver drug metabolism reliably. Abnormal values for three tests that usually indicate that drugs will be metabolized poorly by the liver are high serum bilirubin concentration, low serum albumin concentration, and a prolonged prothrombin time. Bilirubin is metabolized by the liver, and albumin and clotting factors are manufactured by the liver, so aberrant values for all three of these tests are a more reliable indicator of abnormal liver drug metabolism. The Child-Pugh score,[29] a widely used clinical classification for liver disease that incorporates clinical signs and symptoms (ascites and hepatic encephalopathy), in addition to these three laboratory tests, can be used as an indicator of a patient's ability to metabolize drugs that are eliminated by the liver. A score in excess of 10 suggests very poor liver function. As a general rule, patients with cirrhosis have the most severe decreases in liver drug metabolism. Patients with acute or chronic hepatitis often retain relatively normal or slightly decreased hepatic drug-metabolism capacity. In the absence of specific pharmacokinetic dosing guidelines for a medication, a Child-Pugh score equal to 8 to 9 is grounds for a moderate decrease (~25%) in initial daily drug dose for agents that are metabolized primarily (more than or equal to 60%) hepatically, and a score of 10 or greater indicates that a significant decrease in initial daily dose (~50%) is required for drugs that are metabolized mostly by the liver. It is also important to note that patients with severely impaired liver function often have reduced clearance of renally eliminated drugs as a function of their disease.[30] As in any patient with or without liver dysfunction, initial doses are meant as starting points for dosage titration based on patient response and avoidance of adverse effects.

Because there are no good markers of liver function, clinicians have come to rely on pharmacokinetic parameters derived in various patient populations to compute initial doses of drugs that are eliminated hepatically. Initial doses of many liver-metabolized drugs are computed by determining which disease states and/or conditions the patient has that are known to alter the kinetics of the drug and by using these average pharmacokinetic constants to calculate doses. The patient is then monitored for therapeutic and adverse effects, and drug serum concentrations are obtained to ensure that concentrations are appropriate and to adjust doses, if necessary.

Heart failure is often overlooked as a disease state that can alter drug disposition. Severe heart failure decreases cardiac output and therefore reduces liver blood flow. Theophylline,[31] lidocaine,[32] and drugs with high extraction ratios are compounds whose clearance declines with decreased liver blood flow. Initial dosages of these drugs should be reduced in patients with moderate-to-severe heart failure by 25% to 50% until steady-state concentrations and response can be determined.

Use of Steady-State Drug Concentrations

⑮ Serum drug concentrations are readily available to clinicians to use as guides for the individualization of pharmacotherapy. The therapeutic ranges for several drugs have been identified, and it is likely that new drugs also will be monitored using serum concentrations. Although several individualization methods have been advocated for specific drugs, one simple, reliable method is used commonly. For drugs that exhibit linear pharmacokinetics, C_{ss} changes proportionally with the dose. To adjust a patient's pharmacotherapy, a reasonable starting dose is administered for an estimated three to five half-lives. A serum concentration is obtained, assuming that it will reflect C_{ss}. Independent of the route of administration, the new dose (D_{new}) needed to attain the desired C_{ss} ($C_{ss,new}$) is calculated: $D_{new} = D_{old}(C_{ss,new}/C_{ss,old})$, where D_{old} and $C_{ss,old}$ are the old dose and old C_{ss}, respectively. To use this method, $C_{ss,old}$ must reflect steady-state conditions. An assessment of adherence to the regimen should be conducted prior to ordering serum concentrations and prior to adjusting dose based on the results. For example, a patient may have missed doses due to inability to procure their medications because of lack of transportation to the pharmacy or may routinely ration doses due to the cost of the medication. In the inpatient setting, doses also can be missed if the patient is absent from his or her room at the time medications are to be administered. If $C_{ss,old}$ is much larger or smaller than expected for the D_{old} the patient is taking, one should investigate potential reasons for nonadherence and address them with the patient and the healthcare team. Once addressed, repeat the serum concentration determination after another three to five half-lives or change the patient's dose cautiously and monitor for signs of toxicity or lack of effect.

Measurement of Pharmacokinetic Parameters in Patients

⑯ If it is necessary to determine the kinetic constants for a patient to individualize his or her dose, a small kinetic evaluation is conducted in the individual. In these cases, the number of serum concentrations obtained from the patient is held to the minimum needed to calculate accurate pharmacokinetic parameters and doses. The reason for using fewer serum drug concentration determinations is to be as cost-effective as possible because these laboratory tests generally cost $50 to $100 each.

Although many drugs follow two-compartment-model pharmacokinetics (especially after IV administration), a one-compartment model can be used to compute kinetic parameters in patients by delaying the first sample until after biphasic distribution has reached pseudoequilibrium with the tissues. Such an approach avoids intensive blood sampling required for characterization of the two-compartment model pharmacokinetic parameter estimates. Because of this, serum concentrations usually are not measured in patients during the distribution phase. Another important reason serum concentration is not measured during the distribution phase for therapeutic drug-monitoring purposes in patients is that drug in the blood and drug in the tissues are not in equilibrium during this time, so that serum concentrations do not reflect tissue concentrations. When drug serum concentrations are obtained in patients for the purpose of assessing efficacy or toxicity, it is important that they be measured in the post-distribution phase when drug in the blood is in equilibrium with drug at the site of action.

In the case where the patient has received enough doses to be at steady state, pharmacokinetic parameters can be computed using a pre-dose minimum concentration and a post-dose maximum concentration. Under steady-state conditions, serum concentrations after each dose are identical, so the pre-dose minimum concentration is the same before each dose (Fig. e6-8). This situation allows the pre-dose concentration to be used to compute both the patient's $t_{1/2}$ and V, where $V = \text{Dose}/(C_{\text{max,ss}} - C_{\text{min,ss}})$. If the drug was given extravascularly or has a significant distribution phase, the post-dose concentration should be determined after absorption or distribution is finished. To ensure that steady-state conditions have been achieved, the patient needs to receive the drug on schedule for at least three to five estimated half-lives. To make sure that this is the case, inpatients should have their medication administration records checked, and the patient's nurse should be consulted regarding missed or late doses. Outpatients should be interviewed about adherence to the prescribed dosage regimen. When adherence with the dosage regimen has been verified, steady-state conditions can be reasonably assumed.

After CL, V, and $t_{1/2}$ have been computed for a patient, the dose and dosage interval necessary to achieve desired steady-state serum concentrations can be calculated using one-compartment-model equations. Specific examples of these methods to calculate initial doses and individualized doses using serum concentrations are discussed later in this chapter for the aminoglycoside and vancomycin antibiotics.

Computational Approaches

Computer programs that aid in the individualization of therapy are available for many different drugs. The most sophisticated programs use nonlinear regression to fit CL and V_D to actual serum concentrations obtained in a patient.[33] After drug doses and serum concentrations are entered, nonlinear least-squares regression programs adjust CL and V_D until the sum of the squared error between actual (C_{act}) and computer predicted concentrations (C_{pred}) is at a minimum $[\Sigma(C_{pred} - C_{act})^2]$[Σ(Cpred−Cact)2]. Once estimates of CL and V_D are available, doses are calculated easily.

Many programs also take into account what the CL and V_D should be on the basis of disease states and conditions present in the patient.[34] Incorporation of expected population-based parameters allows the program to use a limited number of serum concentrations (one or two) to provide estimates of CL and V_D. This type of computer program is called Bayesian because it incorporates portions of Bayes' theorem during the fitting routine.[35] Several pharmacokinetic dosing programs are available to adjust the dose of a variety of drugs. In the case of renally eliminated drugs (eg, aminoglycosides, vancomycin), population estimates for kinetic parameters are generated by entering the patient's age, weight, height, gender, and serum creatinine concentration into the computer program. For hepatically eliminated drugs (eg, phenytoin), population estimates for kinetic parameters are computed using the patient's age, weight, and gender, as well as other factors that might change hepatic clearance, such as the presence or absence of disease states (eg, cirrhosis or heart failure) or other pharmacotherapy that might cause a drug interaction. The population-based estimates of the pharmacokinetic parameters are then modified using nonlinear least-squares regression fits of serum concentrations to result in individualized parameters for the patient. The individualized parameters are used to compute doses for the patient that are expected to result in desired steady-state concentrations of the drug.

Aminoglycosides

Although aminoglycoside pharmacokinetics follow a multicompartment model,[36] a one-compartment model is sufficient to individualize doses in patients due to the relatively rapid biphasic distribution phase of the drug.[37] Aminoglycosides usually are given as short- term intermittent IV infusions and administered as a single daily dose (extended interval dosing) or multiple doses per day (conventional dosing). Initial doses for aminoglycosides can be computed using estimated kinetic parameters derived from population pharmacokinetic studies. The elimination rate constant is estimated using the patient's creatinine clearance in the following formula:

$\text{k}(\text{in hr}^{-1}) = 0.00293(\text{CL}_{\text{cr}}) + 0.014$k(in hr−1)=0.00293(CLcr)+0.014

where CL_{cr} is the creatinine clearance in milliliters per minute. The volume of distribution is estimated using the average population value for normal-weight (within 30% of ideal weight) individuals equal to

$$V_D = 0.26\ \mathrm{L/kg}\ (V = 0.26[\mathrm{weight}])$$
VD=0.26 L/kg (V=0.26[weight])

Because aminoglycosides are highly hydrophilic, the V_D approximates the extracellular fluid. As such, the ideal body weight (IBW) is used for patients who are of normal weight. IBW can be calculated with the following formulas:

$$\begin{aligned} \mathrm{IBW_{males}[in\ kilograms]} &= 50 + 2.3\ [\mathrm{Ht} - 60] \\ \mathrm{IBW_{females}[in\ kilograms]} &= 45 + 2.3[\mathrm{Ht} - 60] \end{aligned}$$
IBWmales[in kilograms] = 50+2.3 [Ht – 60]IBWfemales[in kilograms] = 45+2.3[Ht – 60]

where Ht is the patient's height in inches. For patient whose actual or total body weight (TBW) is less than their IBW, the TBW is used. To adjust for excess adipose tissue, an adjusted body weight is used instead of ideal for obese individuals (more than 30% of ideal weight).[38] This weight can be calculated by adding 40% of the difference between actual and ideal body weight to the ideal weight. Adjusted BW = IBW + 0.4(TBW – IBW). Additional volume of distribution population estimates are available for other disease states and conditions that cause alterations in extracellular fluid, such as cystic fibrosis,[39] ascites,[40] and neonates.[41]

Aminoglycoside antibiotics exhibit concentration-dependent bacterial killing and also continue to kill susceptible bacteria even after the concentrations are below the minimum bactericidal range. This phenomenon is known as the post-antibiotic effect. Because the post-antibiotic effect is longer with higher concentrations, multiple investigators studied the possibility of giving a higher dose of aminoglycoside using an extended-dosage interval (24 hours or longer, depending on kidney function). Generally, these studies have shown comparable microbiologic and clinical cure rates for many infections and about the same rate of nephrotoxicity (~5%-10%) as with conventional dosing. Ototoxicity has not been monitored using audiometry in most of these investigations, but loss of hearing in the conversational range, as well as signs and symptoms of vestibular toxicity, usually has been assessed and found to be similar to that with aminoglycoside therapy dosed conventionally. Based on these data, clinicians are using extended-interval dosing as the preferred method for most patients. Most clinical guidelines recommend the use of extended-interval dosing, with exceptions notably for combination therapy in Enterococcus spp. catheter-related infections or infective endocarditis.[42–46] Empiric dosing is usually weight-based, with different ranges based on disease state, likely pathogen, local susceptibility rates, and kidney function of the patient. For example, in Pseudomonas aeruginosa infections where the organism has an expected (MIC) $\asymp$ 2 mg/L, peak concentrations between 20 and 30 mg/L (mcg/mL; 40 and 65 μmol/L) and trough concentrations less than 1 mg/L (mcg/mL; 2 μmol/L) for gentamicin or tobramycin have been suggested.[47] However, because of the post-antibiotic effect of aminoglycosides, many institutions target an undetectable trough.

At the present time, there is no consensus on how to approach concentration monitoring using this mode of administration. Some clinicians obtain steady-state peak and trough concentrations and use the kinetic equations to adjust the dose and dosage interval in order to attain appropriate target levels. Other clinicians measure only trough concentrations, trusting that the large doses administered to patients achieve adequate peak concentrations. Emerging evidence has also suggested the AUC monitoring may be the preferred indicator for aminoglycosides; however, no consensus has been reached regarding targets of this dosing method.[48] An international, multiorganization position paper endorsed the use of AUC-based monitoring for patients with critical illness but also provided guidance for more traditional C_{max} and $_{min}$ monitoring with goal $C_{max,ss}$/MIC ratio of ≥ 8-10 and $C_{min,ss}$ of <0.5 mg/L for gentamicin/tobramycin and <2.5 mg/dL for amikacin.[49]

Several nomograms to aid in the dosing of extended interval aminoglycosides have been proposed (Table e6-4).[47,50,51] Weight-based dosing, which is set at either 5 or 7 mg/kg of gentamicin or tobramycin depending on the nomogram, is intended to reach minimum $C_{max,ss}$ values of at least 8 to 10 times the MIC of most organisms, with the initial dosage interval set according to the patient's CL_{cr}. The nomograms also assume patients have a V_D that falls within expected parameters, so these tools are not intended to be used with patients with known alterations in V_D, such as patients with cystic fibrosis or who are pregnant. Many institutions have developed their own nomograms based on one or multiple of the nomograms noted and customized to their patient population, but most have not been validated.

TABLE e6-4

Selected Nomograms for Dosing of Extended Interval Aminoglycosides

Creatinine Clearance	Recommended interval
Hartford[a] and Barnes-Jewish Hospital[b]	
≥60 mL/min	Every 24 hours
40 to 59 mL/min	Every 36 hours
20 to 39 mL/min	Every 48 hours
<20 mL/min	Dosed on levels
University of Rochester[b]	
≥60 mL/min	Every 24 hours
30 to 59 mL/min	Every 36 hours
<30 mL/min	Dosed on levels

Values for creatinine clearance expressed in units of mL/min are converted to mL/s by multiplying by 0.0167.

[a] 7mg/kg dosing utilized

[b] 5 mg/kg dosing utilized.

Data from References 47, 50, and 51.

Once appropriate steady-state serum concentrations are selected, the dosage interval required to achieve those concentrations is calculated, and τ is rounded to a clinically acceptable value (eg, 8, 12, 18, 24, 36, or 48 hours). The formula is as follows:

$$\tau = \frac{ln\ C_{\max,\mathrm{ss}} - ln\ C_{\min,\mathrm{ss}}}{k} + T$$

τ=ln Cmax,ss−ln Cmin,ssk+T

Finally, a dose is computed for the patient using the one-compartment-model intermittent IV infusion equation at steady state. The dose is rounded, usually to the nearest 20 or 40 mg because the vial is supplied in a concentration of 40 mg/mL:

$$D = TkV_\mathrm{D}C_{\max,\mathrm{ss}}\frac{1 - e^{-k\tau}}{1 - e^{-kT}}$$

D=TkVDCmax,ss1−e−kτ1−e−kT

For example, patient JJ is a 65-year-old male (he/him) who weighs 80 kg (176 lb), 6-ft-tall (72 in. or 183 cm) and has been diagnosed with hospital acquired pneumonia caused by Pseudomonas aeruginosa with an MIC of 2 mg/L to tobramycin. His serum creatinine concentration is 2.1 mg/dL (186 µmol/L) and is stable. Compute an extended interval dosing regimen (infused over 1 hour) for tobramycin this patient that would achieve an approximate $C_{\max,\mathrm{ss}}$ of 25 mg/L and $C_{\min,\mathrm{ss}}$ of 0.5 mg/L.

The patient is within 30% of his ideal body weight ($\mathrm{IBW}_\mathrm{male}$ = 50 + 2.3 [72 in – 60] = 78 kg) and has stable kidney function, so the Cockcroft-Gault CL_cr estimation equation can be used:

$$\mathrm{CL}_\mathrm{Cr} = \frac{(140 - 65) \times 78}{72 \times 2.1} = 38\ \mathrm{mL/min}$$

CLCr=(140−65)×7872×2.1=38 mL/min

The patient's weight and estimated CL_cr are used to compute his V_D, k, and $t_{½}$ respectively:

$$V_D = 0.26\ \mathrm{L/kg} \times 78\ \mathrm{kg} = 20.3\ \mathrm{L}$$

VD=0.26 L/kg× 78 kg=20.3 L

$$k = 0.00293(38\ \mathrm{mL/min}) + 0.014 = 0.125\ \mathrm{hr}^{-1}$$

k=0.00293(38 mL/min)+0.014=0.125 hr−1

$$t_{1/2} = \frac{0.693}{0.125\ h^{-1}} = 5.5\ \mathrm{hr}$$

t12=0.6930.125 h−1=5.5 hr

The dosage interval and dose for the desired serum concentrations would then be calculated:

$$\tau = \frac{\ln\ 25\ \mathrm{mg/L} - \ln\ 0.5\ \mathrm{mg/L}}{0.125\ h^{-1}} + 1\ h = 32\ \mathrm{hr}$$

τ=ln 25 mg/L−ln 0.5 mg/L0.125 h−1+1 h=32 hr

The next reasonable dosage interval would then be every 36 hours.

$$D = 1\ \mathrm{hr} \times 0.125\ \mathrm{hr}^{-1} \times 20.3\ \mathrm{L} \times 25\ \mathrm{mg/L} \times \frac{1 - e^{-0.125\ \mathrm{hr}^{-1}(36\ \mathrm{hr})}}{1 - e^{-0.125\ \mathrm{hr}^{-1}(1\ \mathrm{hr})}} = 534\ \mathrm{mg}$$

D=1 hr×0.125 hr−1×20.3 L×25 mg/L×1−e−0.125 hr−1(36 hr)1−e−0.125 hr−1(1 hr)=534 mg

Rounding to the nearest 40 mg increment, we would arrive at a dose of 520 mg. Thus, the prescribed dose would be gentamicin 520 mg every 36 hours administered as a 1-hour infusion.

If appropriate aminoglycoside serum concentrations are available, kinetic parameters can be calculated at any point in therapy. When the patient is not at steady state, serum aminoglycoside concentrations are obtained approximately 2 hours after a dose administered as an IV infusion of 1 hour to allow for drug distribution (C_{max}) and at one additional post-dose time (C_2) at least one estimated half-life after C_{max}, generally between 6 and 10 hours post-dose. The $t_{1/2}$ and k values are computed using C_{max} and C_2:

$$k = \frac{ln\ C_{\max} - ln\ C_2}{\Delta t}$$

k=ln Cmax−ln C2Δt

where Δt is the time that expired between the times C_{max} and C_2 were obtained. If the patient is at steady state, serum aminoglycoside concentrations can be obtained either in the method above or before a dose ($C_{min,ss}$) and after a dose administered as an IV infusion of ~1 hour or as a 30-minute infusion followed by a 30-minute waiting period to allow for drug distribution ($C_{max,ss}$). Because the patient is at steady state, it can be assumed that $C_{min,ss}$ is identical for each dosage interval. The $t_{1/2}$ and k values are computed using $C_{max,ss}$ and $C_{min,ss}$:

$$k = \frac{ln\ C_{\mathrm{max,ss}} - ln\ C_{\mathrm{min,ss}}}{\tau - T}$$

k= ln Cmax,ss−ln Cmin,ssτ−T

Assuming a one-compartment model, the following equation is used to compute V_D:

$$V_D = \frac{{}^{D}/_{T}\left(1 - e^{-kT}\right)}{k(C_{\mathrm{max,ss}} - C_{\mathrm{min,ss}}\ e^{-kT})}$$

VD=DT(1−e−kT)k(Cmax,ss−Cmin,ss e−kT)

where *D* is the dose, and *T* is the duration of infusion. Once these are known, the dose and dosage interval can be calculated for any desired $C_{max,ss}$ and $C_{min,ss}$ with the dose and interval formulas above, remembering to round the dose and dosage interval to provide clinically accepted values (every 24, 36, and 48 hours for dosage interval, nearest 20-40 mg for extended interval dosing).

To provide an example of this technique, the problem given previously will be extended to include steady-state concentrations. Patient JJ was prescribed gentamicin 560 mg every 36 hours (infused over 1 hour) for the treatment of Pseudomonas aeruginosa pneumonia. Steady-state trough ($C_{min,ss}$) and peak ($C_{max,ss}$) values were obtained before and after the fourth dose was given (more than 3-5 estimated half-lives), respectively, and equaled $C_{min,ss}$ = 1.1 mg/L and $C_{max,ss}$ = 24.5 mg/L. Clinically, the patient was improving with decreased white blood cell counts and body temperatures and a resolving chest radiograph. However, the serum creatinine value had increased to 2.5 mg/dL (221 µmol/L). Because of this, a new dosage regimen with a similar peak (to maintain high intrapulmonary levels) but lower trough (to decrease the risk of drug-induced nephrotoxicity) concentrations was targeted. The patient's elimination rate constant and half-life can be computed using the following formulas:

$$k = \frac{\ln\ 24.5\ \mathrm{mg/L} - \ln\ 1.1\ \mathrm{mg/L}}{36\ \mathrm{hr} - 1\ \mathrm{hr}} = 0.089\ \mathrm{hr}^{-1}$$

k=ln 24.5 mg/L−ln 1.1 mg/L36 hr−1 hr=0.089 hr−1

$$t_{1/2} = \frac{0.693}{0.089\ \mathrm{hr}^{-1}} = 7.8\ \mathrm{hr}$$

t12= 0.6930.089 hr−1=7.8 hr

The patient's volume of distribution can be calculated using the following equation:

$$V_D = \frac{520\ \mathrm{mg}/1\ \mathrm{hr}\ \left(1 - e^{-0.089\ \mathrm{hr}^{-1} \times 1\ \mathrm{hr}}\right)}{0.089\ \mathrm{hr}^{-1}\left(24.5\ \mathrm{mg/L} - \left[1.1\ \mathrm{mg/L} \times e^{-0.089 \times 1\ \mathrm{hr}}\right]\right)} = 21.2\ \mathrm{L}$$

VD=520 mg/1 hr (1−e−0.089 hr−1×1 hr)0.089 hr−1(24.5 mg/L−[1.1 mg/L×e−0.089×1 hr])=21.2 L

Thus, the patient's volume of distribution was larger and half-life was longer than originally estimated; this led to higher serum concentrations than anticipated. To achieve the desired serum concentrations ($C_{min,ss}$ = 0.5 mg/L and $C_{max,ss}$ = 25 mg/L), the patient's actual kinetic parameters are used to compute a new dose and dosage interval:

$$\tau = \frac{\ln\ 25\ \mathrm{mg/L} - \ln\ 0.5\ \mathrm{mg/L}}{0.089\ \mathrm{hr}^{-1}} = 44\ \mathrm{hr}$$

τ=ln 25 mg/L−ln 0.5 mg/L0.089 hr−1=44 hr

The next reasonable dose interval would be every 48 hours. Then, calculate the dose:

$D = 1\ \text{hr} \times 0.089\ \text{hr}^{-1} \times 21.2\ \text{L} \times 25\ \text{mg/L} \times \frac{1 - e^{-0.089\ \text{hr}^{-1}(48\ \text{hr})}}{1 - e^{-0.089\ \text{hr}^{-1}(1\ \text{hr})}} = 546\ \text{mg}$D=1 hr×0.089 hr−1×21.2 L×25 mg/L×1−e−0.089 hr−1(48 hr)1−e−0.089 hr−1(1 hr)=546 mg

This result could be rounded to the nearest 20 mg increment (540 mg) or rounded down to nearest 40 mg increment (520 mg, which the patient had previously reached goal $C_{\text{max,ss}}$). Given that the patient is improving, one could choose to round to previous dose, and the new regimen would be tobramycin 520 every 48 hours and infused over 1 hour, with the first dose given 48 hours (eg, the new dosage interval) after the last dose of the old dosage regimen.

To illustrate how the nomogram dosage would be used, the same patient example used previously will be repeated for this dosage approach. Patient JJ weighs 80 kg (176 lb) and has a CL_{cr} of 38 mL/min. Using the Harford nomogram, the patient would receive tobramycin 560 mg every 48 hours (7 mg/kg× 80 kg = 560 mg; the initial dosage interval for CL_{cr} = 38 mL/min is every 48 hours).[47] In addition to providing empiric dosing, the three referenced nomograms also contain a nomogram for adjusting interval based on a random serum concentration drawn between 6- and 14-hours post-dose, with each having slight variation in time frame.[47,50,51] The nomograms contain a concentration vs time graph that the concentration is plotted on that will suggest the recommended interval based on that concentration/time profile. For example, ten hours after the first dose was given, the serum tobramycin concentration for Patient JJ was 6.9 mg/L (mcg/mL; 8.6 nmol/L). According to the graph contained in the Hartford nomogram, the dosage interval should be changed to every 36 hours. The new dose is 560 mg every 36 hours.[47]

Vancomycin

Vancomycin requires multicompartment models to completely describe its serum-concentration-versus-time curves. However, if peak serum concentrations are obtained after the distribution phase is completed (usually 30 minutes to 1 hour after a 1-hour IV infusion), a one-compartment model can be used for patient dosage calculations.[52] Also, because vancomycin has a relatively long half-life compared with the infusion time, only a small amount of drug is eliminated during infusion, and it is usually unnecessary to use more complex IV infusion equations. Thus, simple IV bolus equations can be used to calculate vancomycin doses for most patients. It has been known that the ideal PK/PD parameter for vancomycin activity is an AUC over 24 hours to MIC ratio of ≥400; however, in the recent past, monitoring of steady-state trough concentrations of vancomycin in patients with serious methicillin-resistant Staphylococcus aureus (MRSA) infections was seen as an appropriate surrogate marker of AUC/MIC ratio.[53] Previous consensus guidelines recommended a vancomycin trough of 15-20 mg/L (mcg/mL; 10.4-13.8 µmol/L) for serious infections, such as infective endocarditis, bacteremia, osteomyelitis, meningitis, and pneumonia, caused by MRSA. Other indications are often treated with a reduced trough goal of 10 to 15 mg/L (mcg/mL; 6.9-10.4 µmol/L), though there is little evidence to support either of these practices. It has been recommended that vancomycin troughs be maintained a >10 mg/L (mcg/mL; 6.9 µmol/L) in order to avoid development of resistance.[53]

Recent evidence and the increased availability of software programs that allow for clinicians to estimate AUC_0^{24}AUC024 have led to a shift in consensus guidelines, which now recommend AUC-guided dosing for serious MRSA infections.[54] The goal AUC, assuming an MIC of 1 mg/L, is defined as 400 to 600 mg*hr/L. It should be noted that the consensus guidelines found insufficient evidence to recommend either AUC-guided or trough-guided dosing in patients with non-invasive MRSA or other infections requiring the use of vancomycin. As such, institutions may use one or both of these dosing strategies, and it is prudent that pharmacists understand both methods of dosing.

Regardless of method, the empiric dose of vancomycin for patients with normal kidney function is 15 to 20 mg/kg every 8 or 12 hours, with consideration for patient-specific factors.[54] For patients with impaired kidney function, the interval will need to be extended to prevent accumulation of drug. A loading dose of 20 to 35 mg/kg can be considered for patients in which therapeutic drug concentrations are needed quickly, such as critical illness.[54]

Trough-Guided Approach

Initial doses of vancomycin can be computed for adult patients using estimated kinetic parameters derived from population pharmacokinetic data. Several pharmacokinetic prediction models have been proposed to describe estimation of parameters; however, none have shown to be more reliable than the other.[55]

The most commonly used prediction model in practice is the Matzke equation, in which the elimination rate constant can be calculated with the following equation: $k = 0.00083(\text{CL}_{\text{cr}}) + 0.0044$.[56] The volume of distribution is computed assuming the standard value of 0.7 L/kg: $V_D = 0.7(\text{Wt})$, where

Wt is the patient's weight.

Another prediction model, commonly referred to as the Bauer method, in which clearance is estimated using the patient's creatinine clearance in the following equation[57,58]: CL (in mL/min/kg) = 0.695 (CL_{cr} in mL/min/kg) + 0.05. The elimination rate constant is calculated using clearance and volume of distribution estimates, correcting for possible differences in units for these parameters: $k = CL/V_D$.

$C_{max,ss}$ values of between 20 and 40 mg/L (and $C_{min,ss}$ values of between 10 and 15 mg/L typically are used for patients with mild-to-moderate infections or sensitive bacteria with lower MIC values (less than 1 mcg/mL). For patients with pneumonia or other life- threatening infections due to multidrug-resistant organisms, $C_{min,ss}$ as high as 15 to 20 mg/L were previously suggested, though an AUC-guided approach is now recommended for invasive MRSA infections as above.[53,54] After appropriate steady-state concentrations are chosen, the dosage interval required to attain those concentrations is computed, and τ is rounded to a clinically acceptable value (8, 12, 18, 24, 36, 48, or 72 hours):

$$\tau = \frac{\ln C_{\max,ss} - \ln C_{\min,ss}}{k}$$

τ=ln Cmax,ss−ln Cmin,ssk

Finally, the maintenance dose is computed for the patient using a one-compartment-model IV bolus equation at steady state, and the dose is rounded off to the nearest 250 mg:

$$D = C_{\max,ss} V_D (1 - e^{-k\tau})$$

D=Cmax,ssVD(1−e−kτ)

If desired, a loading dose can be computed using the following equation, with a goal of attaining a C_{max} that is similar to the desired $C_{max,ss}$:

$$LD = V_D C_{\max,ss}$$

LD=VDCmax,ss

The following case will illustrate the use of this dosage methodology. Patient HJ is a 65-year-old female (she/her) who weighs 68 kg (150 lb) and is 5 ft 10 in. (70 in. [178 cm]) tall. She has developed a skin and soft tissue infection with abscess; Staphylococcus aureus is the suspected pathogen with an anticipated MIC = 1 mg/L. Her serum creatinine concentration is 1.8 mg/dL (159 µmol/L) and is stable. Compute a vancomycin dosage regimen that would provide approximate peak (obtained 1 hour after a 1-hour infusion) and trough concentrations of 30 and 12 mg/L (mcg/mL; 21 and 8 µmol/L), respectively.

The patient is at her ideal body weight (IBW_{female}= 45.5 kg + 2.3[70 in. – 60 in.] = 68 kg), and has stable kidney function, so the Cockcroft-Gault creatinine clearance estimation formula can be used: CL_{cr} = 0.85([140 – 65 y]68 kg)/(72[1.8 mg/dL]) = 33 mL/min (0.55 mL/s). The patient's weight and CL_{cr} are used to calculate her estimated V_D, k, and $t_{1/2}$ using the Matzke equation:

$$V_D = 0.7\ \text{L/kg} \times 68\ \text{kg} = 47.6\ \text{L}$$

VD=0.7 L/kg×68 kg=47.6 L

$$k = 0.00083(CL_{cr}) + 0.0044 = 0.00083(33\ \text{mL/min}) + 0.0044 = 0.032\ \text{hr}^{-1}$$

k=0.00083(CLcr)+0.0044=0.00083(33 mL/min)+0.0044=0.032 hr−1

$$t_{1/2} = \frac{0.693}{0.032} = 22\ \text{hr}$$

t1/2=0.6930.032=22 hr

The dosage interval, maintenance dose, and loading dose for the desired serum concentrations can be computed:

$$\tau = \frac{\ln 30\ \text{mg/L} - \ln 12\ \text{mg/L}}{0.032\ \text{hr}^{-1}} = 28.6\ \text{hr}$$

τ=ln 30 mg/L−ln 12 mg/L0.032 hr−1=28.6 hr

The closest reasonable interval would be every 24 hours. Next, the maintenance dose can be calculated:

$$D = 30\ \text{mg/L} \times 47.6\ \text{L} \times \left(1 - e^{-0.032\ \text{hr}^{-1} \times 24\ \text{hr}}\right) = 765\ \text{mg}$$

D=30 mg/L×47.6 L ×(1−e−0.032 hr−1×24 hr)=765 mg

Rounded to nearest 250 mg, the dose would be 750mg. A loading dose could be used as follows:

$$LD = 47.6\ \text{L} \times 30\ \text{mg/L} = 1428\ \text{mg}$$

LD=47.6 L×30 mg/L=1428 mg

Rounded to the nearest 250mg, the loading dose would be 1,500 mg. Therefore, the prescribed dose would be vancomycin 1,500 mg IV once as a loading dose, followed by vancomycin 750mg IV every 24 hours administered as a 1-hour infusion thereafter. If a loading dose is used, it would be given as the first dose, and the first maintenance dose would be administered one dosage interval later.

To calculate the expected $C_{max,ss}$ and $C_{min,ss}$, the following equations can be used:

$$C_{\max,ss} = \frac{D}{V_D \cdot T \cdot k} \times \frac{(1 - e^{-kT})}{(1 - e^{-k\tau})}$$

Cmax,ss=DVD · T · k×(1−e−kT)(1−e−kτ)

$$C_{\min,ss} = C_{\max,ss} e^{-k(\tau - T)}$$

Cmin,ss=Cmax,sse−k(τ−T)

In the example above, a dose of vancomycin 750 mg IV every 24 hours administered over a 1-hour infusion would produce an estimated $C_{max,ss}$ and

$C_{\text{min,ss}}$ as below:

$$C_{\text{max,ss}} = \frac{750 \ \text{mg}}{47.6 \ \text{L} \cdot 1 \ h \cdot 0.032 \ h^{-1}} \times \frac{\left(1 - e^{-0.032 \ h^{-1} \times 1 \ h}\right)}{\left(1 - e^{-0.032 \ h^{-1} \times 24 \ h}\right)} = 28.9 \ \text{mg}/\text{L}$$

Cmax,ss=750 mg47.6 L · 1 h · 0.032 h−1×(1−e−0.032 h−1×1 h)(1−e−0.032 h−1×24 h)=28.9 mg/L

$$C_{\text{min,ss}} = \frac{28.9 \ \text{mg}}{L} \times e^{-0.032(24-1)} = 13.8 \ \text{mg}/\text{L}$$

Cmin,ss=28.9 mgL×e−0.032(24−1)=13.8 mg/L

In this case, the calculated estimated $C_{\text{max,ss}}$ and $C_{\text{min,ss}}$ are within the designated parameters.

For routine monitoring, many clinicians measure only steady-state vancomycin trough concentrations in patients. The justification for this approach is that because vancomycin exhibits time-dependent bacterial killing, the minimum concentration is the most important with regard to therapeutic outcome. Vancomycin pharmacokinetics also support this approach because the volume of distribution is relatively stable and is not changed by many disease states or conditions. Because of this important point, it is difficult to attain peak steady-state concentrations in the toxic range when the steady-state vancomycin trough is in the therapeutic range if typical doses are used (15 mg/kg or ≍ 1,000 mg for average-weight individuals). Also, toxic peak concentrations (generally greater than 80-100 mg/L [mcg/mL; 55-69 µmol/L]) are quite a bit higher than therapeutic peak concentrations, which adds a safety margin between effective concentrations and those yielding adverse drug effects.

When trough-only monitoring of vancomycin concentrations is chosen by a clinician, a simple variant of linear pharmacokinetics can be used to adjust the dose (D) and dosage interval (τ):

$$\frac{D_{\text{new}}}{\tau_{\text{new}}} = \left(\frac{D_{\text{current}}}{\tau_{\text{current}}}\right)\left(\frac{C_{\text{ss,new}}}{C_{\text{ss,current}}}\right)$$

Dnewτnew=(Dcurrentτcurrent)(Css,newCss,current)

where new and current indicate the new target trough concentration and the current measured trough concentration, respectively. This equation is an approximation of the actual new steady-state trough concentration that will be attained in the patient because, mathematically, $C_{\text{ss,new}}$ is an exponential function of τ.

An example of this approach is given in the following case. Patient MK is a 72 year old man (he/him) who weighs 72 kg (158 lb) and measures 5 ft 9 in. (69 in. [175 cm]). He was prescribed vancomycin 1,000 mg every 12 hours (infused over 1 hour) for the treatment of an S. epidermidis central venous catheter infection. A steady-state trough ($C_{\text{min,ss}}$) value was obtained before the fifth dose was given (more than three to five estimated half-lives), and $C_{\text{min,ss}} = 19$ mg/L . Clinically, the patient was improving, but the trough concentration was judged to be too high. Because of this, a modified dosage regimen with a $C_{\text{min,ss}} = 10$ mg/L was suggested.

$$\frac{D_{\text{new}}}{\tau_{\text{new}}} = \left(\frac{1000 \ \text{mg}}{12 \ \text{hr}}\right)\left(\frac{10 \ \text{mg}/\text{L}}{19 \ \text{mg}/\text{L}}\right) = 44 \ \text{mg}/\text{hr}$$

Dnewτnew=(1000 mg12 hr)(10 mg/L19 mg/L)=44 mg/hr

Because the patient is near his ideal weight, the same dose of 1,000 mg can be used (D_{new}), and the new dosage interval (τ_{new}) can be computed: $\tau =$ 1,000 mg/44 mg/hr = 23 hr, rounded to 24 hours. The new prescribed dose for the patient would be 1,000 mg every 24 hours.

AUC-Guided Approach

The preferred method to implement AUC-guided dosing includes using Bayesian software to support dosing; however, these programs may be cost-prohibitive.[59] Alternatively, several other calculators and programs are available that use first-order pharmacokinetic equations, including spreadsheet-based, electronic health record-based, and commercial calculators.[59] These programs require multiple steady state serum concentrations to calculate patient-specific pharmacokinetic parameters. When Bayesian software is available, two serum concentrations can be drawn after the first dose and input into the model, which will recommend maintenance dosing to achieve AUC/MIC goals. If using first-order equations, two serum concentrations can be drawn and then patient-specific parameters to calculate an estimated AUC for patients with serious MRSA infections or dosed based on population parameters; however, two serum concentrations will need to be drawn at steady state in order to confirm AUC goals are achieved.

Remembering that AUC is equal to the dose divided by clearance,

$$\text{AUC} = \frac{D}{CL}$$

AUC=DCL

The approach to dosing vancomycin based on an AUC-guided approach requires estimation of vancomycin clearance. As discussed previously in the chapter, clearance is the product of k and V_D:

$$CL = k \times V_D$$

CL=k×VD

Where k and V_D can be calculated using the Matzke equation as in the trough-based approach section. Then, once clearance has been estimated, the AUC equation can be re-arranged to solve for total daily dose (TDD):

$$\mathrm{TDD} = \mathrm{CL} \times \mathrm{AUC}_0^{24}\ _{\mathrm{goal}}$$

TDD=CL×AUC024 goal

As the goal is between 400 to 600 mg*hr/L, most clinicians choose 500 mg*hr/L to allow rounding of doses and interval in later steps while still remaining within AUC goal. Alternatively, a range could be calculated using the lowest and highest goal and selecting a dose that falls within that range. Next, the interval must be calculated. $C_{max,ss}$ values of 40 mg/L and $C_{min,ss}$ values of 10 mg/L are typically used to maximize efficacy while reducing nephrotoxicity and preventing resistance.[60] After appropriate steady-state concentrations are chosen, the dosage interval required to attain those concentrations is computed, and τ is rounded to a clinically acceptable value (8, 12, 18, 24, 36, 48, or 72 hours):

$$\tau = \frac{\ln C_{\max,ss} - \ln C_{\min,ss}}{k}$$

τ=ln Cmax,ss−ln Cmin,ssk

Finally, a maintenance dose is chosen using calculated:

$$D = \frac{TDD}{24/\tau}$$

D=TDD24/τ

Using the patient case described above, this time with an AUC-guided approach, will illustrate the use of this dosage methodology. Patient CW is a 65-year-old female (she/her) who weighs 68 kg (150 lb) and is 5 ft 10 in. (70 in. [178 cm]) tall. She is found to have developed Methicillin-resistant Staphylococcus aureus bacteremia with an MIC = 1 mg/L. Her serum creatinine concentration is 1.8 mg/dL (159 µmol/L) and is stable. Compute a vancomycin dosage regimen that would provide approximate AUC of 400 to 600 mg*hr/L.

The patient is at her ideal body weight (IBW_{female}= 45.5kg + 2.3[70 in. – 60in.] = 68 kg) and has stable kidney function, so the Cockcroft-Gault creatinine clearance estimation formula can be used: CL_{cr} = 0.85([140 – 65 y]68 kg)/(72[1.8 mg/dL]) = 33 mL/min (0.55 mL/s). The patient's weight and CL_{cr} are used to calculate her estimated V_D, k, and $t_{1/2}$ using the Matzke equation:

$$V_D = 0.7\ \mathrm{L/kg} \times 68\ \mathrm{kg} = 47.6\ \mathrm{L}$$

VD=0.7 L/kg×68 kg=47.6 L

$$k = 0.00083(\mathrm{CL_{cr}}) + 0.0044 = 0.00083(33\ \mathrm{mL/min}) + 0.0044 = 0.032\ \mathrm{hr}^{-1}$$

k=0.00083(CLcr)+0.0044=0.00083(33 mL/min)+0.0044=0.032 hr−1

$$t_{1/2} = \frac{0.693}{0.032} = 22\ \mathrm{hr}$$

t1/2=0.6930.032=22 hr

Using the population pharmacokinetic parameter estimate, clearance and subsequently TDD can be calculated.

$$CL = k \times V_D = 0.032\ \mathrm{hr}^{-1} \times 47.6\ \mathrm{L} = 1.52\ \mathrm{L/hr}$$

CL=k×VD=0.032 hr−1×47.6 L=1.52 L/hr

$$TDD = \mathrm{CL} \times \mathrm{AUC}_0^{24}\ goal = 1.52\ \mathrm{hr/L} \times 500\ \mathrm{mg \cdot hr/L} = 762\ \mathrm{mg}$$

TDD=CL×AUC024 goal=1.52 hr/L×500 mg · hr/L=762 mg

The dosage interval and maintenance dose for the desired serum AUC goal can then be computed:

$$\tau = \frac{\ln\ 40\ \mathrm{mg/L} - \ln\ 10\ \mathrm{mg/L}}{0.032\ \mathrm{hr}^{-1}} = 43\ \mathrm{hr}$$

τ=ln 40 mg/L−ln 10 mg/L0.032 hr−1=43 hr

The closest reasonable interval would be every 48 hours. Then, the maintenance dose to be given at the interval is calculated:

$$D = \frac{762\ \mathrm{mg}}{24\ \mathrm{hr}/48\ \mathrm{hr}} = 1524\ \mathrm{mg}$$

D=762 mg24 hr/48 hr=1524 mg

Rounded to nearest 250 mg, the dose would be 1500 mg. Therefore, the prescribed dose would be vancomycin 1,500 mg IV every 48 hours.

Once at steady state, two serum concentrations (which will be referred to as C_1 and C_2) can be obtained to ensure AUC goals are being met. Ideally, the first concentration should be drawn 1-2 hours after the end of the infusion and the second should be a trough, immediately preceding the next scheduled dose. Then, patient-specific elimination constant can be calculated using the following equations:

$$k = \frac{ln\ C_1 - ln\ C_2}{t_1 - t_2}$$

k= ln C1−ln C2t1−t2

Where t_1 and t_2 (often represented as Δt) are the time after the start of the infusion when C_1 and C_2 were drawn, respectively. Because serum concentrations are rarely drawn at the exact peak and trough of a dosing regimen, adjustments are needed to be able to calculate the $C_{max,ss}$ and $C_{min,ss}$. Once the patient's pharmacokinetic parameters are known, the true $C_{max,ss}$ can be calculated as follows:

$$C_{max,ss} = \frac{C_1}{e^{-k(\Delta t)}}$$

Cmax,ss=C1e−k(Δt)

Where Δt is the difference between the time C1 was drawn and the end of the infusion. Then, $C_{min,ss}$ can be calculated:

$$C_{min,ss} = C_2 \times e^{-k(\Delta t)}$$

Cmin,ss=C2×e−k(Δt)

Where Δt is the difference between the time C_2 was drawn and the end of the dosing interval. As a reminder, the trough should be maintained >10 mg/L. The patient-specific V_D can then be calculated using the $C_{max,ss}$:

$$V_D = \frac{(D/T)(1-e^{-kT})}{k(C_{max,ss})(1-e^{-k\tau})}$$VD=(D/T)(1−e−kT)k(Cmax,ss)(1−e−kτ)

Then, the AUC can be calculated:

$$AUC_0^{24} = \frac{TDD}{k \times V_D}$$AUC024=TDDk×VD

If AUC is within goal range of 400 to 600 mg*hr/L, the current dose should continue. If it is not within goal, the dose may be adjusted using the following equation:

$$TDD_{\text{new}} = \frac{TDD_{\text{current}}}{AUC_{\text{current}}} \times AUC_{\text{goal}}$$TDDnew= TDDcurrentAUCcurrent×AUCgoal

As an illustration of responding to two-concentration AUC monitoring, the following case will be used. Patient LG was started on vancomycin 1,000 mg IV every 12 hours administered as a 1-hour infusion for treatment of MRSA infective endocarditis. At steady state, two concentrations were obtained: 35.1 mg/L drawn 1.5 h after the end of the infusion and 11.1 mg/L drawn 10.5 h after the end of the infusion (0.5 h before the end of the dosing interval).

First, the patient specific k should be calculated:

$$k = \frac{\ln 35.1 \text{ mg/L} - \ln 11.1 \text{ mg/L}}{10.5 - 1.5} = 0.128 \text{ hr}^{-1}$$k=ln 35.1 mg/L−ln 11.1 mg/L10.5−1.5=0.128 hr−1

Then, $C_{max,ss}$ and $C_{min,ss}$ can be calculated:

$$C_{\text{max,ss}} = \frac{35.1 \text{ mg/L}}{e^{-0.128 \text{ hr}^{-1}(1.5 \text{ hr})}} = 42.5 \text{ mg/L}$$Cmax,ss=35.1 mg/Le−0.128 hr−1(1.5 hr)=42.5 mg/L

$$C_{\text{min,ss}} = 11.1 \times e^{-0.128 \text{ hr}^{-1}(0.5 \text{ hr})} = 10.4 \text{ mg/L}$$Cmin,ss=11.1×e−0.128 hr−1(0.5 hr)=10.4 mg/L

The V_D can then be calculated:

$$V_D = \frac{1000 \text{ mg}/_{1 \text{ hr}}\left(1 - e^{-0.128 \text{ hr}^{-1} \times 1 \text{ hr}}\right)}{0.128 \text{ hr}^{-1}\left(35.1 \text{ mg/L}\right)\left(1 - e^{-0.128 \text{ hr}^{-1} \times 12 \text{ hr}}\right)} = 34.1 \text{ L}$$VD=1000 mg1 hr(1−e−0.128 hr−1×1 hr)0.128 hr−1(35.1 mg/L)(1−e−0.128 hr−1×12 hr)=34.1 L

Finally, the AUC can be calculated, remembering that in this equation total daily dose is used instead of single dose:

$$AUC_0^{24} = \frac{2000 \text{ mg}}{0.128 \text{ hr}^{-1} \times 34.1 \text{ L}} = 458 \text{ mg} * \text{hr/L}$$AUC024=2000 mg0.128 hr−1×34.1 L=458 mg*hr/L

Because the AUC is within goal of 400 to 600 mg*hr/L, the patient's previous dosing of vancomycin 1,000 mg IV every 12 hours should be continued.

Knowledge of pharmacokinetic principles will help the clinician individualize vancomycin dosing to maximize efficacy and minimize toxicity for optimized patient care.

CLINICAL PHARMACODYNAMICS

⑰ Pharmacodynamics is the study of the relationship between the concentration of a drug and the response obtained in a patient. Originally, investigators examined the dose–response relationship of drugs in humans but found that the same dose of a drug usually resulted in different concentrations in individuals because of pharmacokinetic differences in clearance and volume of distribution. Examples of quantifiable pharmacodynamic measurements include changes in blood pressure during antihypertensive pharmacotherapy, decreases in heart rate during beta blocker treatment, and alterations in prothrombin time or international normalized ratio during warfarin therapy.

For drugs that exhibit a direct and reversible effect, the following diagram describes what occurs at the level of the drug receptor:

$$Drug + receptor \leftrightarrow drug - receptor\ complex \leftrightarrow response$$Drug+receptor↔drug−receptor complex↔response

According to this scheme, there is a drug receptor located within the target organ or tissue. When a drug molecule “finds” the receptor, it forms a complex that causes the pharmacologic response to occur. The drug and receptor are in dynamic equilibrium with the drug–receptor complex.

E_{max} and Sigmoid E_{max} Models

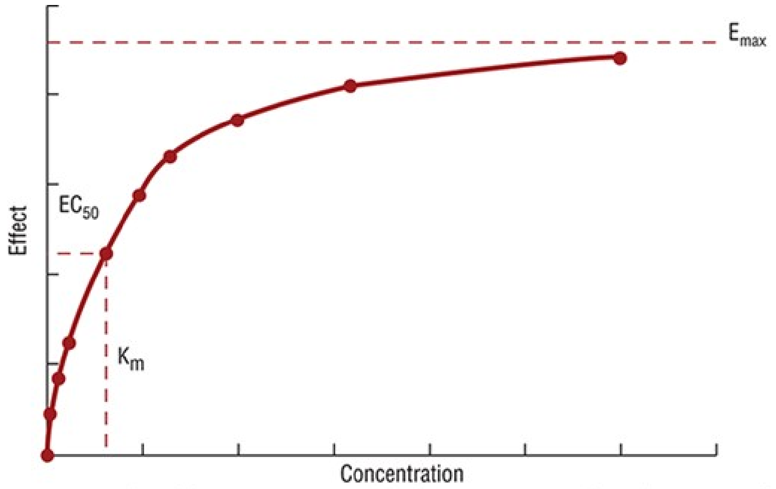
The mathematical model that comes from the classic drug–receptor theory shown previously is known as the E_{max} model:

$$E = \frac{E_{\max} \times C}{EC_{50} + C}$$E=Emax×CEC50+C

where E is the pharmacologic effect elicited by the drug, E_{max} is the maximum effect the drug can cause, EC_{50} is the concentration causing one-half the maximum drug effect ($E_{max}/2$), and C is the concentration of drug at the receptor site. EC_{50} can be used as a measure of drug potency (a lower EC_{50}, indicating a more potent drug), whereas E_{max} reflects the intrinsic efficacy of the drug (a higher E_{max}, indicating greater efficacy) or maximal capacity to which a given drug can produce an effect. If pharmacologic effect is plotted against concentration in the $_{max}$ equation, a hyperbola results with an asymptote equal to E_{max} (Fig. e6-10). At a concentration of zero, no measurable effect is present.

FIGURE e6-10

The E_{max} model has the shape of a hyperbola with an asymptote equal to E_{max}. EC_{50} is the concentration where effect = $E_{max}/2$.



Source: Joseph T. DiPiro, Gary C. Yee, L. Michael Posey, Stuart T. Haines, Thomas D. Nolin, Vicki L. Ellingrod: *DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e*

When dealing with human studies in which a drug is administered to a patient, and pharmacologic effect is measured, it is very difficult to determine the concentration of the drug at the receptor site. Because of this, serum concentrations (total or unbound) usually are used as the concentration parameter in the E_{max} equation. Therefore, the values of E_{max} and EC_{50} are much different than if the drug were added to an isolated tissue or cell culture in a laboratory setting.

The result is that a much more empirical approach is used to describe the relationship between concentration and effect in clinical pharmacology studies. After a pharmacodynamic experiment has been conducted, concentration–effect plots are generated. The shape of the concentration–effect curve is used to determine which pharmacodynamic model will be used to describe the data. Because of this, the pharmacodynamic models used in a clinical pharmacology study are deterministic in the same way that the shape of the serum-concentration-versus-time curve determines which pharmacokinetic model is used in clinical pharmacokinetic studies.

Sometimes a hyperbolic function does not describe the concentration–effect relationship at lower concentrations adequately.

When this is the case, the sigmoid E_{max} equation may be superior to the E_{max} model:

$$E = \frac{E_{\max} \times C^n}{EC_{50}^n + C^n}$$

E=Emax×CnEC50n+Cn

where *n* is an exponent that changes the shape of the concentration–effect curve. When n greater than 1, the concentration–effect curve is S- or sigmoid-shaped at lower serum concentrations. When *n* less than 1, the concentration–effect curve has a steeper slope at lower concentrations.

With both the E_{max} and sigmoid E_{max} models, the largest changes in drug effect occur at the lower end of the concentration scale. Small changes in low serum concentrations cause large changes in effect. As serum concentrations become larger, further increases in serum concentration result in smaller changes in effect. Using the E_{max} model as an example and setting E_{max} = 100 units and EC_{50} = 20 mg/L, doubling the serum concentration from 5 to 10 mg/L increases the effect from 20 to 33 units (a 67% increase), whereas doubling the serum concentration from 40 to 80 mg/L only increases the effect from 67 to 80 units (a 19% increase). This is an important concept for clinicians to remember when doses are being titrated in patients.

Linear Models

When serum concentrations obtained during a pharmacodynamic experiment are between 20% and 80% of E_{max}, the concentration–effect curve may appear to be linear. This occurs often because lower drug concentrations may not be detectable with the analytic technique used to assay serum samples, and higher drug concentrations may be avoided to prevent toxic side effects. The equation used is that of a simple line: $E = S \times C + I$, where E is the drug effect, C is the drug concentration, S is the slope of the line, and I is the y intercept. In this situation, the value of S can be used as a measure of drug potency (the larger the value of S, the more potent the drug). The linear model can be derived from the E_{max} model. When EC_{50} is much greater than C, $E = (E_{max}/EC_{50})C = S \times C$, where $S = E_{max}/EC_{50}$.

The linear model allows a nonzero value for effect when the concentration equals zero. This may be a baseline value for the effect that is present without the drug, the result of measurement error when determining effect, or model misspecification. Also, this model does not allow the prediction of a maximum response.

Some investigators have used a log-linear model in pharmacodynamic experiments: $E = S \times (\log C) + I$, where the symbols have the same meaning as in the linear model. The advantages of this model are that the concentration scale is compressed on concentration–effect plots for experiments where wide concentration ranges were used, and the concentration values are transformed so that linear regression can be used to compute model parameters. The disadvantages are that the model cannot predict a maximum effect or an effect when the concentration equals zero. With the increased availability of nonlinear regression programs that can compute the parameters of nonlinear functions such as the E_{max} model easily, use of the log-linear model has been discouraged.[61]

Baseline Effects

At times, the effect measured during a pharmacodynamic study has a value before the drug is administered to the patient. In these cases, the drug changes the patient's baseline value. Examples of these types of measurements are heart rate and blood pressure. In addition, a given drug may increase or decrease the baseline value. Two basic techniques are used to incorporate baseline values into pharmacodynamic data. One way incorporates the baseline value into the pharmacodynamic model; the other transforms the effect data to take baseline values into account.

Incorporation of the baseline value into the pharmacodynamic model involves the addition of a new term to the previous equations. E_0 is the symbol used to denote the baseline value of the effect that will be measured. The form that these equations takes depends on whether the drug increases or decreases the pharmacodynamic effect. When the drug increases the baseline value, E_0 is added to the equations:

$$E = E_0 + \frac{E_{\max} \times C}{EC_{50} + C}$$
E=E0+Emax×CEC50+C

$$E = E_0 + \frac{E_{\max} \times C^n}{EC_{50}^n + C^n}$$
E=E0+Emax×CnEC50n+Cn

$$E = E_0 + S \times C$$
E=E0+S×C

When E_0 is not known with any better certainty than any other effect measurement, it should be estimated as a model parameter similar to the way that one would estimate the values of E_{max}, EC_{50}, S, or n.[62,63] If the baseline effect is well known and has only a small amount of measurement error, it can be subtracted from the effect determined in the patient during the experiment and not estimated as a model parameter. This approach can lead to better estimates of the remaining model parameters.[63] Using the linear model as an example, the equation used would be $E - E_0 = S \times C$.

If the drug decreases the baseline value, the drug effect is subtracted from E_0 in the pharmacodynamic models:

$$E = E_0 - \frac{E_{\max} \times C}{IC_{50} + C}$$
E=E0−Emax×CIC50+C

$$E = E_0 - \frac{E_{\max} \times C^n}{IC_{50}^n + C^n}$$
E=E0−Emax×CnIC50n+Cn

$$E = E_0 - S \times C$$
E=E0−S×C

where E_{max} represents the maximum reduction in effect caused by the drug, and IC_{50} is the concentration that produces a 50% inhibition of E_{max}. These forms of the equations have been called the inhibitory E_{max} and inhibitory sigmoidal respectively. In this arrangement of the pharmacodynamic model, E_0 is a model parameter and can be estimated. If the baseline effect is well known and has little measurement error, the effect in the presence of the drug can be subtracted from the baseline effect and not estimated as a model parameter. Using the inhibitory E_{max} model as an example, the formula would be $E_0 - E = (E_{max} \times C)/(IC_{50} + C)$.

When using the inhibitory E_{max} model, a special situation occurs if the baseline effect can be obliterated completely by the drug (eg, decreased premature ventricular contractions during antiarrhythmic therapy). In this situation, $E_{max} = E_0$, and the equation simplifies to a rearrangement known as the fractional E_{max} equation:

$$E = E_0\left(1 - \frac{C}{IC_{50} + C}\right)$$

E=E0(1−CIC50+C)

This form of the model relates drug concentration to the fraction of the maximum effect.

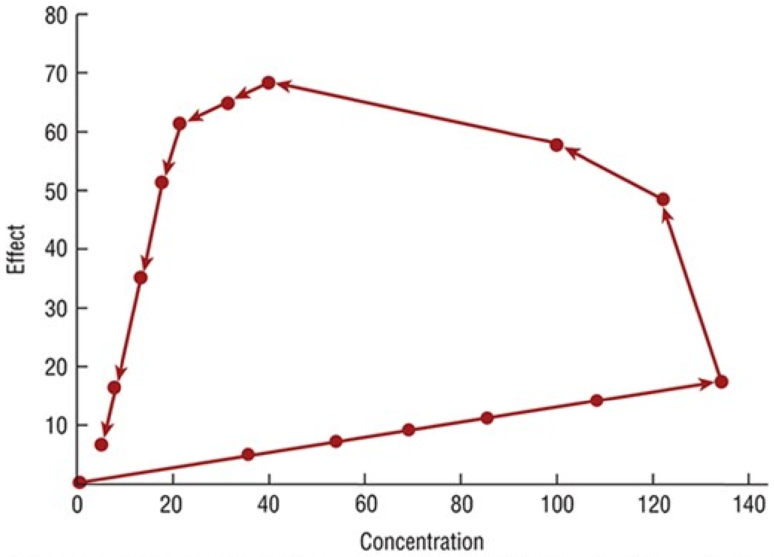
An alternative approach to the pharmacodynamic modeling of drugs that alter baseline effects is to transform the effect data so that they represent a percentage increase or decrease from the baseline value.[63] For drugs that increase the effect, the following transformation equation would be used: percent effect $_t$ = ([treatment$_t$ –baseline]/baseline) × 100. For drugs that decrease the effect, the following formula would be applied to the data: percent inhibition$_t$ = ([baseline – treatment$_t$]/baseline) × 100. The subscript indicates the treatment, effect, or inhibition that occurred at time t during the experiment. If the study included a placebo control phase, baseline measurements made at the same time as treatment measurements (heart rate determined 2 hours after placebo and 2 hours after drug treatment) could be used in the appropriate transformation equation.[63] The appropriate model (excluding E_0) then would be used.

Hysteresis

Concentration–effect curves do not always follow the same pattern when serum concentrations increase as they do when serum concentrations decrease. In this situation, the concentration–effect curves form a loop that is known as hysteresis. With some drugs, the effect is greater when serum concentrations are increasing, whereas with other drugs, the effect is greater while serum concentrations are decreasing (Fig. e6-11). When individual concentration–effect pairs are joined in time sequence, this results in clockwise and counterclockwise hysteresis loops.

FIGURE e6-11

Hysteresis occurs when effect measurements are different at the same concentration. This is commonly seen after short-term IV infusions or extravascular doses where concentrations increase and subsequently decrease. Counterclockwise hysteresis loops are found when concentration–effect points are joined as time increases (shown by arrows) and effect is larger at the same concentration but at a later time. Clockwise hysteresis loops are similar, but the concentration–effect points are joined in clockwise order, and the effect is smaller at a later time.



Source: Joseph T. DiPiro, Gary C. Yee, L. Michael Posey, Stuart T. Haines, Thomas D. Nolin, Vicki L. Ellingrod: *DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e*
Copyright © McGraw Hill. All rights reserved.

Clockwise hysteresis loops usually are caused by the development of tolerance to the drug. In this situation, the longer the patient is exposed to the drug, the smaller is the pharmacologic effect for a given concentration. Therefore, after an extravascular or short-term infusion dose of the drug, the effect is smaller when serum concentrations are decreasing compared with the time when serum concentrations are increasing during the infusion or absorption phase.

Accumulation of a drug metabolite that acts as an antagonist also can cause clockwise hysteresis. Counterclockwise hysteresis loops can be caused by the accumulation of an active metabolite, sensitization to the drug, or delay in time in equilibration between serum concentration and concentration of drug at the site of action. In this case, the same concentration will cause an increased effect upon prolonged systemic drug exposure. Combined pharmacokinetic/pharmacodynamic models have been devised that allow equilibration lag times to be taken into account.

CONCLUSION

The availability of inexpensive, rapidly achievable serum drug concentration measurements has changed the way clinicians monitor pharmacotherapy in patients. The therapeutic range for many drugs is known and can be used to guide therapy or pharmacokinetic principles can be applied to determine dose adjustments; however, clinicians must remember that significant pharmacodynamic variability exists between patients and serum concentrations should never replace clinical judgment. Three kinetic constants determine the dosage requirements of patients. Clearance determines the maintenance dose ($MD = CLC_{ss}$), volume of distribution determines the loading dose ($LD = V_DC_0$), and half-life determines the time to steady state and the dosage interval. Several methods are available to compute these parameters. Methods available to individualize pharmacotherapy range from clinical pharmacokinetic techniques using simple mathematical relationships that hold for all drugs that obey linear pharmacokinetics to very complex computer programs that are specific to one drug.

As the use of increasingly complex drug therapies expands and the role of therapeutic drug monitoring evolves, it is becoming more imperative than ever that clinicians understand the principles of pharmacokinetics and pharmacodynamics. Therapeutic monitoring is no longer relegated to a consultant kinetics services—it impacts the day-to-day practice of many healthcare professionals. Whether managing immunosuppressants in a transplant clinic, adjusting antiepileptic pharmacotherapy for a patient with seizures to manage a drug-drug interaction, or initiating AUC-guided vancomycin to treat a serious bacterial infection, clinical pharmacokinetics is being utilized across the healthcare system every day. By thoughtfully considering these principles, clinicians can select the drug dose, route, and frequency that will provide the optimal balance of safety and efficacy for the patient and promote positive outcomes. In all, clinical pharmacokinetics and pharmacodynamics help healthcare professionals provide optimal, individualized care to patients.

ABBREVIATIONS

α	distribution rate constant
AUC	area under serum or blood-concentration-versus-time curve
β	terminal rate constant
C	serum concentration
C_{max}	maximum serum or blood concentration
C_{min}	minimum serum or blood concentration
C_0	initial concentration
C_{SS}	steady-state concentration
$C_{ss,\,ub}$	steady-state concentration of unbound drug

CL	clearance
CLcr	creatinine clearance
CL_{int}	intrinsic clearance
D	dose
E	extraction ratio
F	fraction of drug absorbed into the systemic circulation
f_u	fraction of drug in the blood that is unbound
k	elimination rate constant
k_a	absorption rate constant
K_m	serum concentration at which the rate of metabolism equals $V_{max}/2$
LD	loading dose
MD	maintenance dose
P-gp	P-glycoprotein
Q	blood flow
R_0	IV infusion rate
τ	dosage interval
t'	post-infusion time
$t_{1/2}$	half-life
V_D	volume of distribution
V_{max}	maximum rate of drug metabolism

SELF-ASSESSMENT QUESTIONS

1. Systemic clearance is the pharmacokinetic parameter that describes:

    A. Absorption

    B. Bioavailability

    C. Distribution

    D. Elimination

2. In pharmacokinetic studies, it is found that 80% of the drug reaches systemic circulation. The *F* for this drug would be:

    A. 0.2

    B. 0.8

    C. 1.2

    D. 1.8

3. A drug that is given as an IV bolus is found to produce serum concentrations of 10 mg/L when measured 4 hours after the dose and 5 mg/L when measured 10 hours after the dose. The half-life of the drug can be calculated as:

   A. 2 hrs

   B. 5 hrs

   C. 6 hrs

   D. 15 hrs

4. Phenytoin displays saturable Michaelis-Menten kinetics. If the dose is increased, the serum concentration is predicted to be _____ than expected in linear kinetics.

   A. Proportionally higher

   B. Disproportionally higher

   C. Proportionally lower

   D. Disproportionally lower

5. Which of the following is most likely to undergo extensive first-pass metabolism?

   A. Low extraction ratio drug given IV

   B. High extraction ratio drug given IV

   C. Low extraction ratio drug given orally

   D. High extraction ratio drug given orally

6. Most drugs follow nonlinear pharmacokinetics:

   A. True

   B. False

7. The enzyme system responsible for the metabolism of most drugs is:

   A. P-glycoprotein

   B. Serum creatinine

   C. Cytochrome P450

   D. HMG-CoA

8. Pharmacodynamics is best described as:

   A. Relationship of dose and serum concentration

   B. Relationship of serum concentration and response

   C. Relationship of dose over time

   D. Relationship of half-life and steady state

9. For a drug that is renally eliminated, which would be the most appropriate to assess to determine if dose adjustments are needed?

    A. Estimated glomerular filtration rate

    B. Child-Pugh score

    C. International normalized ratio (INR)

    D. Adjusted body weight

10. Compartmental models are helpful in order to:

    A. Predict plasma drug concentrations with a dosage regimen

    B. Correlate drug concentrations with activity or toxicity

    C. Estimate how a disease state may affect drug concentrations in the body

    D. All of the above

11. The area under the curve is best defined as:

    A. Total exposure of the body to the drug over time

    B. Time to reduce serum concentrations by one-half

    C. Proportionality constant that relates the amount of drug in the body to the serum concentration

    D. Volume of plasma cleared of the given drug over time

12. The half-life is best defined as:

    A. Total exposure of the body to the drug over time

    B. Time to reduce serum concentrations by one-half

    C. Proportionality constant that relates the amount of drug in the body to the serum concentration

    D. Volume of plasma cleared of the given drug over time

13. The range of concentrations within which the pharmacologic response is produced and adverse effects prevented in most patients is referred to as the:

    A. $E_{\max}$

    B. Steady-state concentration

    C. Fraction unbound drug

    D. Therapeutic window

14. The volume of distribution is best defined as:

    A. Total exposure of the body to the drug over time

    B. Time to reduce serum concentrations by one-half

    C. Proportionality constant that relates the amount of drug in the body to the serum concentration

D. Volume of plasma cleared of the given drug over time

15. For a drug that is hepatically eliminated, which would be the most appropriate to assess to determine if dose adjustments are needed?

A. Estimated creatinine clearance

B. Child-Pugh score

C. Alkaline phosphatase

D. Adjusted body weight

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** Systemic clearance is a pharmacokinetic parameter that describes the process of elimination.

2. **B.** The bioavailability (F), which is defined as the proportion of drug absorbed into systemic circulation, has a maximum value of 1. Thus, the percentage (80%) needs to be converted to ratio form –0.8.

3. **C.** The half-life is calculated by determining the amount of time for the serum concentration to reduce by one-half. The serum concentration in this example goes from 10 mg/L to 5 mg/L (a 50% reduction) in 6 hours, so this is the half-life.

4. **A.** Michaelis-Menten kinetics are nonlinear kinetics that result from saturable elimination processes. As such, increases in dose would result in disproportionately higher than expected serum concentrations than a drug with linear kinetics.

5. **D.** High extraction ratio drugs are very effectively metabolized by the liver. When drugs are given orally, they pass through the liver prior to reaching systemic circulation, thus limiting the bioavailability of high extraction ratio drugs. This does not occur with intravenously administered drugs, which enter the bloodstream directly.

6. **B.** Most drugs follow linear kinetics.

7. **C.** The group of enzymes primarily responsible for drug metabolism are the Cytochrome P450 enzymes. There are many unique enzymes within this group.

8. **B.** Pharmacodynamics is the interaction of the serum concentration and response, ie, what the drug does to the body.

9. **A.** Estimated GFR or creatinine clearance can be used for assessing kidney function.

10. **C.** Compartmental models are useful for all of the listed items—predicting plasma (or tissue) drug concentrations with a dosage regimen, correlating drug concentrations with activity or toxicity, and estimating how a disease state may affect drug concentrations in the body

11. **A.** The area under the curve is the measurement of the total exposure (area) of the drug to the body over the entire course of time, from administration of the drug to the end of elimination.

12. **B.** The half-life is the time to reduce the serum concentration by one-half. The time it takes to reduce serum concentration from 20 mg/L to 10 mg/L as it takes to reduce from 2 mg/L to 1 mg/L.

13. **D.** The therapeutic window describes the range of serum concentrations in which there is maximal effect with minimal adverse effects in the large population. This does not guarantee safety and efficacy in an individual patient.

14. **C.** The volume of distribution is a pharmacokinetic parameter that describes distribution and is a proportionality constant of that relates the serum concentration to the total amount of drug in the body.

15. **B.** The Child-Pugh score can be used to estimate degree of liver impairment in patients with hepatic disease. Alkaline phosphatase may be elevated in acute hepatitis and is not reliably indicative of the metabolizing ability of the liver.

Chapter e7: Clinical Pharmacogenomics

Roseann S. Gammal; Larisa H. Cavallari; Y. W. Francis Lam

KEY CONCEPTS

KEY CONCEPTS

① Genetic variation contributes to pharmacokinetic and pharmacodynamic properties of medications.

② Genetic variation affects drug-metabolizing enzymes, transporters, and target proteins, as well as immune-related proteins that may impact medication response.

③ Genetic polymorphisms may influence medication effectiveness and risk for toxicity.

④ Pharmacogenomics is the study of the impact of genetic polymorphisms on medication response.

⑤ The goals of pharmacogenomics are to optimize medication efficacy and limit toxicity based on an individual's DNA.

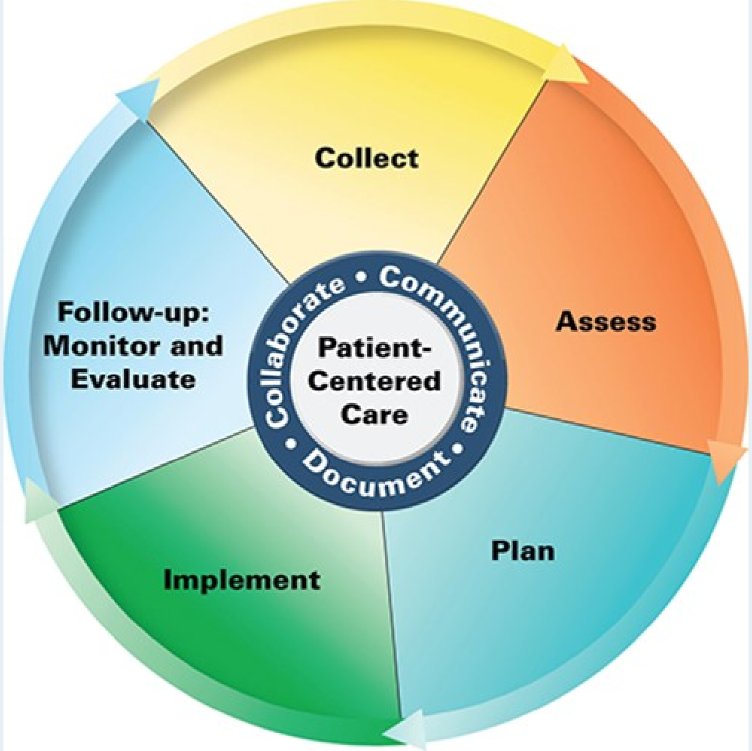
⑥ Single nucleotide polymorphisms are the most common gene variations associated with medication response.

⑦ Evidence-based resources, such as US Food and Drug Administration medication labels, Clinical Pharmacogenetics Implementation Consortium Guidelines, and the Pharmacogenomics Knowledgebase, are available to help clinicians select and dose medications based on a patient's genetic profile.

⑧ The pharmacist plays a key role in advancing pharmacogenomics in clinical practice as part of a multidisciplinary healthcare team.

PATIENT CARE PROCESS

Patient Care Process for Application of Pharmacogenomics



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient characteristics (eg, age, sex, pregnancy)
- Patient medical history (personal and family)
- Current medications including OTC use, herbal products, dietary supplements
- Pharmacogenomic test results that are relevant to a patient's care (eg, *CYP2C19* genotype if the patient is being considered for clopidogrel therapy)

Assess

- Pharmacogenomic test results, including translating genotype to phenotype to drug therapy recommendation (see Tables e7-4, e7-6, and e7-7)
- Impact of genetic variation on pharmacokinetics and/or pharmacodynamics (see Fig. e7-3)
- Medication-related problems that may be related to genetic variability, even when a pharmacogenomic test has not been done
- Disease implications of pharmacogenomic test results and refer the patient to a genetics-trained healthcare provider when necessary
- Predisposition to disease and drug response
- Quality and source of existing pharmacogenomic test results
- Actionable versus non-actionable pharmacogenomic test results using high quality, evidence-based pharmacogenomics databases, and clinical guidelines (see Table e7-8)
- Cost, cost-effectiveness, and reimbursement issues relevant to pharmacogenomic tests and services

Plan*

- Integrate pharmacogenomic test results with other clinical variables to optimize medication therapy (see Fig. e7-6)
- Recommend pharmacogenomic testing when appropriate.

Implement[*]

- Pharmacogenomics-guided care plan
- Document pharmacogenomic test results in the electronic health record

Follow-Up: Monitor and Evaluate

- Presence of medication-related adverse effects
- Pharmacogenomics-guided care plan

[*] *Collaborate with patients, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Visit the CPIC Website: https://cpicpgx.org/. Select and review a gene-drug guideline. Briefly describe how these recommendations may be applied to clinical practice. This activity is intended to build your experience with accessing pharmacogenomic guidelines and how they may be integrated into prescribing decisions.

INTRODUCTION

Great variability exists among individuals in response to medication therapy, and it is difficult to predict how effective or safe a medication will be for a particular patient. For example, when treating a patient with depression, it may be necessary to try several agents or a combination of agents before achieving adequate depressive symptom control with acceptable tolerability. Several clinical factors are known to influence medication response, including age, body size, kidney and liver function, and concomitant medication use. However, considering these factors alone is often insufficient in predicting the likelihood of medication efficacy or safety for a given patient. For example, identical antidepressant therapy in two patients of similar age, sex, race, and with similar medical histories and concomitant medication therapy may produce inadequate control of depressive symptoms in one patient and intolerable adverse effects in the other.

① ② The observed interpatient variability in medication response may result largely from genetically determined differences in drug metabolism, distribution, and target proteins. The influence of heredity on medication response was demonstrated as early as 1956 with the discovery that an inherited deficiency of glucose-6-phosphate dehydrogenase (G6PD) was responsible for hemolytic reactions to the antimalarial drug primaquine (Fig. e7-1). Variations in genes encoding cytochrome P450 (CYP) and other drug-metabolizing enzymes are now well-recognized as causes of interindividual differences in plasma concentrations of certain medications. These variations may have serious implications for medications with a narrow therapeutic index such as warfarin, phenytoin, and mercaptopurine. Other variations associated with medication response occur in genes for drug transporters such as the solute carrier organic anion transporter (OAT) family member 1B1 (SLCO1B1) as well as drug targets such as receptors and enzymes. Genetic variations for drug-metabolizing enzymes and transporter proteins may influence drug disposition, thus altering pharmacokinetic properties. Drug target genes may alter pharmacodynamic mechanisms by affecting sensitivity to a medication at its target site. Variation in immune-related genes, such as those that encode human leukocyte antigen (HLA) molecules, may affect a patient's predisposition to severe medication hypersensitivity reactions despite having no direct effect on pharmacokinetic or pharmacodynamic mechanisms.

PHARMACOGENOMICS: A DEFINITION

③ ④ Pharmacogenomics, the field of study at the intersection of pharmacology and genomics, involves the search for genetic variations that lead to interindividual differences in medication response. The term *pharmacogenetics* often is used interchangeably with the term *pharmacogenomics*. Historically, pharmacogenetics referred to variation in a single gene that affects medication response, whereas pharmacogenomics referred to the entire spectrum of genes that interact to determine medication efficacy and safety. For example, a pharmacogenetic study examines the influence of the *CYP2C9* gene on warfarin dose requirements. Conversely, a pharmacogenomic study might examine the interaction between the *CYP2C9*, vitamin K oxidoreductase complex subunit 1 (*VKORC1*), and *CYP4F2* genes on warfarin dose requirements. Given that multiple proteins are involved in determining the ultimate response to most medications, many investigators are taking a more pharmacogenomic approach to elucidating genetic contributions to medication response. However, most examples of pharmacogenetic testing in clinical practice today involve single genes. Based on the current usage of the terms, this chapter treats pharmacogenetics and pharmacogenomics as synonymous.

⑤ The goals of clinical pharmacogenomics are to optimize medication therapy and limit toxicity based on an individual's genetic profile. Thus, clinical pharmacogenomics aims to use genetic information to choose a medication and dose that will have the greatest likelihood for achieving therapeutic outcomes with the least potential for harm in a given patient. Pharmacogenomic discoveries have provided opportunities for clinicians to use genetic tests to predict individual responses to medication and specifically select medications for patients based on identified genetic variants. Genotype-guided therapy is already a reality for some diseases, such as cancer and cystic fibrosis, where novel medications have been developed to target specific genetic mutations. Clinical implementation of pharmacogenomics has also emerged in other therapeutic areas, including cardiology, psychiatry, neurology, pain management, and infectious disease.

HUMAN GENOME PROJECT AND SUBSEQUENT EFFORTS IN PRECISION MEDICINE

While the discovery of genetic contributions to medication response dates back to the 1950s, interest in clinical pharmacogenomics began in earnest with the sequencing of the human genome in 2003 (Fig. e7-1). The final version from the Human Genome Project contains 99% of the gene-containing sequence, with 99.9% accuracy. The International HapMap Project followed the Human Genome Project and aimed to identify common patterns of heritability, called haplotypes, in the human genome. This enabled genome-wide association studies that led to discoveries of previously unsuspected variants linked to medication response, including a variant in the *CYP2C18-CYP2C19-CYP2C9-CYP2C8* gene cluster linked to warfarin dose requirement in persons of African ancestry.[1]

The Clinical Pharmacogenetics Implementation Consortium (CPIC), which is funded by the National Institutes of Health, provides evidence-based guidelines describing how to use pharmacogenomic test results to optimize medication therapy (Table e7-1). The US Food and Drug Administration

(FDA) also provides gene-based dosing guidance for certain medications in their labeling. See the "Pharmacogenomic Medication Labeling and Guidelines" section for more information about these and other pharmacogenomics resources. Other major efforts funded by the US government to advance precision medicine are described in Table e7-1.

TABLE e7-1

Federally Funded Efforts to Advance Precision Medicine

Year Started	Project Name	Goal
2000	Pharmacogenomics Research Network (PGRN) (www.pgrn.org)[a]	Discover genetic associations with drug response across a number of diseases.
2000	Pharmacogenomics Knowledgebase (PharmGKB) (www.pharmgkb.org)	Collect, curate, and disseminate information about a human genetic variation on drug response.
2002	International HapMap Project (https://www.genome.gov/10001688/international-hapmap-project)	Determine the common patterns of DNA sequence variation in the human genome and make this information freely available in the public domain.
2003	Encyclopedia of DNA Elements (ENCODE) Project (www.encodeproject.org)	Create a catalog of functional elements in the human genome.
2008	1,000 Genomes Project (www.internationalgenomes.org)	Develop a comprehensive catalog of less common genetic variation in the human genome through a DNA sequencing approach.
2009	Clinical Pharmacogenetics Implementation Consortium (CPIC) (cpicpgx.org)	Create consensus-based clinical guidelines on how to use genetic test results to optimize pharmacotherapy.
2014	Implementing Genomics in Practice (IGNITE) Network (https://ignite-genomics.org)	Enhance the use of genomic medicine, including pharmacogenomics, in clinical care.
2015	*All of Us* Research Program (www.allofus.nih.gov)	Build a national research resource of longitudinal data, including genetic data, from at least one million persons in the United StatesU.S. to facilitate novel approaches to prevent and treat disease based on genetic, environmental, and social factors.

[a] Renamed in 2021 as the "Pharmacogenomics Global Research Network."

GENETIC CONCEPTS

The human genome contains more than 3 billion nucleotide base pairs, which include approximately 20,000 protein-coding genes. Two purine nucleotide bases, adenine (A) and guanine (G), and two pyrimidine nucleotide bases, cytosine (C) and thymidine (T), are present in deoxyribonucleic acid (DNA), with purines and pyrimidines always pairing together as A-T and C-G in the two strands that make up the DNA double-helix. Most nucleotide base pairs are identical from person to person, with only 0.1% contributing to individual differences.

According to the central dogma of biology, when one strand of DNA is transcribed into RNA and translated to make a protein, three consecutive nucleotides form a codon. Each codon specifies an amino acid or amino acid chain termination. For example, the nucleotide sequence, or codon, GGA specifies the amino acid glycine. The genetic code has substantial redundancy, in which two or more codons code for the same amino acid. For example, GGC, GGG, and GGT also code for glycine. Amino acids are the basic constituents of proteins, which mediate all cellular functions. Only 20 different amino acids, in various arrangements, form the basic units of all the proteins in the human body.

A gene is a series of codons that specifies a particular protein. Genes contain several regions: *exons* that encode for the final protein, *introns* that consist of intervening noncoding regions, and *regulatory regions* that control gene transcription. Introns may also contain regulatory sequences. In most cases, an individual carries two alleles, one from each parent, at each gene locus. An *allele* is defined as the sequence of nucleic acid bases at a given gene chromosomal locus. Two identical alleles make up a *homozygous* genotype, and two different alleles make up a *heterozygous* genotype. A *phenotype* refers to the outward expression of the genotype. Common genetic terms and their definitions are provided in Table e7-2.

TABLE e7-2

Common Genetic Terms and Their Definitions

Term	Definition
Allele	A version of a gene. An individual inherits two alleles for each gene, one from each parent.
Diplotype	A haplotype pair (eg, two alleles inherited for a particular gene).
Gene	Basic physical unit of inheritance.
Genotype	An individual's collection of genes. Can also refer to the two alleles inherited for a particular gene.
Haplotype	A set of DNA variations that tend to be inherited together.
Heterozygous	Two different alleles inherited for a given gene.
Homozygous	Two identical alleles inherited for a given gene.
Nucleotide	Basic building block of nucleic acids (RNA and DNA). Consists of a sugar molecule (ribose in RNA or deoxyribose in DNA) attached to a phosphate group and a nitrogen-containing base. The bases in DNA are adenine (A), cytosine (C), guanine (G), and thymine (T). In RNA, the base uracil (U) takes the place of thymine.
Phenotype	An individual's observable traits
Polymorphism	One of two or more variants of a particular DNA sequence. The most common type of polymorphism involves variation at a single base pair (ie, single nucleotide polymorphism or SNP).

TYPES OF GENETIC VARIATIONS

Genetic variations occur as either rare defects or polymorphisms. *Polymorphisms* are defined as variations in the genome that occur at a frequency of at least 1% in the human population. For example, the genes encoding the CYP enzymes 2B6, 2C9, 2C19, 2D6, and 3A5 are polymorphic, with functional gene variants of greater than 1% occurring in different biogeographical ancestry groups. In contrast, some variants occur in less than 1% of the population and cause inherited diseases such as cystic fibrosis, hemophilia, and Huntington's disease. Common diseases, such as essential hypertension and Type 2 diabetes mellitus, are polygenic in which multiple genetic polymorphisms in conjunction with environmental factors contribute to the disease susceptibility.

⑥ Single-nucleotide polymorphisms, abbreviated as SNPs and pronounced "snips," are the most common genetic variations in human DNA, occurring once approximately every 300 base pairs. More than 20 million SNPs have been mapped in the human genome. SNPs occur when one nucleotide base pair replaces another, as illustrated in Fig. e7-2. Thus, SNPs are single-base differences that exist between individuals. Nucleotide substitution results in two possible alleles. One allele, typically either the most commonly occurring allele or the allele originally sequenced, is considered the *normal* or *wild type*, and the alternative allele is considered the *variant allele*.

FIGURE e7-2

Nucleotide sequence of the β_2-adrenergic receptor gene from codons 13 to 19. (*A*) Nucleotide sequence of the wild-type allele with adenine (A) at nucleotide position 46 (*underlined*) located in codon 16 of the β_2-adrenergic receptor gene. The AGA codon designates the amino acid arginine (Arg), with an average frequency of 39% in the human population. (*B*) Nucleotide sequence of the variant allele with guanine (G) at nucleotide position 46 (*underlined*), located in codon 16. The GGA codon designates the amino acid glycine (Gly), which occurs at an average frequency of 61%. Although the Arg16 polymorphism occurs less commonly than the Gly16 polymorphism, it is referred to as the wild type because it was identified first.

An SNP may result in amino acid substitution, which may or may not alter the function of the encoded protein. For example, in Fig. e7-2, guanine (G) is substituted for adenine (A) at nucleotide 46 in the β_2-adrenergic receptor gene.[2] This results in the substitution of glycine for arginine at amino acid position (codon) 16 and alterations in receptor downregulation on prolonged exposure to β_2-receptor agonists. SNPs that result in amino acid substitution are referred to as *nonsynonymous*. SNPs that do not result in amino acid substitution are called *synonymous*, which often are silent (ie, have no effect on the resultant protein product). Referring to a previous example of redundancy in the genetic code, replacement of thymine (T) with cytosine (C) in the codon CGT is an example of a synonymous SNP because both CGT and CGC code for arginine. Synonymous SNPs and variants occurring in regulatory regions of the gene are usually abbreviated based on the nucleotides involved and the nucleotide base position. For example, c.3608C > T indicates that either cytosine or thymine may occur, with cytosine occurring most often at position 3608 of a given gene region. Nonsynonymous SNPs usually are designated by the amino acids and codons involved. For example, p.Arg144Cys (or p.R144C using amino acid symbols) indicates that cysteine may be substituted for arginine at codon 144. Alternatively, SNPs may be referred to by their reference SNP number (or rs number, eg, rs12777823), as designated by the National Center for Biotechnology Information SNP database (dbSNP; https://www.ncbi.nlm.nih.gov/snp/). If an SNP changes the amount or function of a protein that contributes to medication response, it may alter pharmacokinetic properties or a patient's sensitivity to a medication or otherwise predispose a patient to adverse medication reactions.

The following are other examples of genetic variants:

1. *Insertion-deletion polymorphisms*, in which a nucleotide or nucleotide sequence is either added to or deleted from a DNA sequence.
2. *Tandem repeats*, in which a nucleotide sequence repeats in tandem (eg, if "AG" is the nucleotide repeat unit, "AGAGAGAGAG" is a five-tandem repeat).
3. *Frameshift mutation*, in which there is an insertion/deletion polymorphism, and the number of nucleotides added or lost is not a multiple of three, resulting in disruption of the gene's reading frame.

4. *Defective splicing*, in which an internal polypeptide segment is abnormally removed, and the ends of the remaining polypeptide chain are joined.
5. *Aberrant splice site*, in which processing of the protein occurs at an alternate site.
6. *Premature stop codon polymorphisms*, in which there is the premature termination of the polypeptide chain by a stop codon (a specific sequence of three nucleotides that do not code for an amino acid but rather specify polypeptide chain termination).
7. *Copy number variants*, in which entire copies of genes or gene segments more than 1 kb in size are duplicated, deleted, or rearranged.

Single nucleotide polymorphisms may occur in exon, intron, or regulatory regions of a gene. Those occurring in exons may alter protein function, whereas those in regulatory regions (eg, the promoter region) may alter gene expression and the amount of protein that is produced. For example, the variant c.-1639 G>A in the promoter region of the *VKORC1* gene alters a transcription factor binding site and results in decreased gene expression and decreased VKORC1 enzyme produced, which is clinically relevant for warfarin dosing.[3] Variations in the intron region may be silent unless they affect intron splicing or otherwise alter gene expression. Multiple SNPs may be in *linkage disequilibrium* with each other. This means that two or more SNPs are inherited together more frequently than would be expected based on chance alone. For example, if there are two possible SNPs, c.-1639 G>A and c-1173 C>T, in a given gene (eg, *VKORC1* in this example), and an A at position -1639 always occurs with a T at position -1173 and vice versa, the two SNPs are said to be in *complete linkage disequilibrium*.[3] A set of SNPs that are inherited together is called a *haplotype*.

Within the field of clinical pharmacogenomics, the "star (*) allele" nomenclature is used. The wild-type allele is denoted as **1* ("star one"). Every other allele is given another number as its name (eg, **2*, **3*, **4*, **5*) to easily distinguish one from the other. Each star allele (ie, haplotype) may be defined by one or more SNPs or other types of genetic variants. Two star alleles together (eg, **1*/**2*), representing one maternal allele and one paternal allele, are referred to as a diplotype or a genotype. In clinical practice, pharmacogenomic testing is often conducted using genotyping rather than sequencing. In other words, laboratories have a prespecified set of SNPs they are looking for rather than identifying each nucleotide in the gene, which would be a more costly approach and lead to the identification of variants of unknown significance.

A limitation of genotyping is that a **1* designation is assigned if none of the prespecified variants was detected for a particular gene. In clinical practice, we would assume the patient to have the "normal" allele, but in reality, the patient could harbor a clinically important genetic variant that was not tested by the lab. Allele frequencies vary across biogeographical ancestry groups; therefore, it is important to assess the variants tested by a clinical laboratory to ensure that they are adequately representative across populations. For example, many labs have traditionally only tested the **2* and **3* alleles for *CYP2C9*, which are the most common alleles associated with a loss of enzyme activity in patients of European ancestry, but not in those of African ancestry in whom the reduced function **5*, **6*, **8*, and **11* occur. Genotyping for *CYP2C9*2* and **3* only in African ancestry populations can lead to misclassifying a large percentage of individuals as normal metabolizers when in fact they have a reduced function allele for which the lab did not test. The Association for Molecular Pathology now publishes guidelines on what alleles should be tested for certain pharmacogenes to ensure appropriate coverage of clinically relevant variants for diverse populations.[4–6]

POLYMORPHISMS IN GENES FOR DRUG-METABOLIZING ENZYMES

② Polymorphisms in the drug-metabolizing enzymes represent the first recognized and, so far, the most documented examples of genetic variants with consequences in medication response and toxicity. The major phase-I enzymes are the CYP superfamily of isoenzymes. *N*-acetyltransferase, uridine diphosphate glucuronosyltransferase (UGT), and glutathione *S*-transferase are examples of phase II metabolizing enzymes that exhibit genetic polymorphisms. Thiopurine *S*-methyltransferase (TPMT) and dihydropyrimidine dehydrogenase (DPD) are examples of nucleotide base-metabolizing enzymes. Genetic variation can lead to a spectrum of drug-metabolizing enzyme activity (ie, phenotypes): poor metabolizer (PM), intermediate metabolizer (IM), normal metabolizer (NM), rapid metabolizer (RM), and ultrarapid metabolizer (UM).[7]

When assessing the effects of genetic variation on drug metabolism, it is important to consider whether the parent drug is active or inactive (ie, a prodrug) and whether it is metabolized into an active or an inactive metabolite (Fig. e7-3). For example, if an active drug is metabolized into an inactive metabolite by a specific enzyme, genetic variation leading to ultrarapid metabolism could yield subtherapeutic plasma concentrations and treatment failure with normal doses. In contrast, decreased metabolism could yield supratherapeutic concentrations and toxicity with normal doses. In the case of a prodrug, the opposite is true (Fig. e7-3). The clinical significance of genetic variation in plasma concentrations of drugs and their metabolites depends on the drug's therapeutic index and number of enzymatic pathways involved.

FIGURE e7-3

The clinical impact of genetic variation on drug metabolism depends on whether the parent drug is active or inactive, and whether its metabolite is active or inactive. (*A*) Active drug converted into an inactive metabolite and (*B*) prodrug (inactive) converted into an active metabolite.

Table e7-3 lists examples of polymorphic metabolizing enzymes and corresponding drug substrates whose plasma concentrations and pharmacologic effects may be altered as a consequence of genetic variation. Examples of such effects are discussed in the following sections.

TABLE e7-3

Examples of Substrates for Drug-Metabolizing Enzymes Exhibiting Genetic Variability

Enzyme	Drug Substrate
CYP2D6	Atomoxetine
	Antipsychotics (aripiprazole, brexpiprazole, iloperidone, pimozide)
	Metoclopramide
	Ondansetron
	Opioid analgesics (codeine, tramadol)
	Selective serotonin reuptake inhibitors (paroxetine, fluvoxamine)
	Tamoxifen
	Tricyclic antidepressants (desipramine, nortriptyline, amitriptyline, imipramine)
	Venlafaxine
	Vortioxetine
CYP2C9	Nonsteroidal anti-inflammatory drugs (celecoxib, flurbiprofen, ibuprofen, meloxicam, piroxicam)
	Phenytoin
	Warfarin
CYP2C19	Clobazam
	Clopidogrel

	Proton pump inhibitors (dexlansoprazole, lansoprazole, omeprazole, pantoprazole)
	Selective serotonin reuptake inhibitors (citalopram, escitalopram, sertraline)
	Tricyclic antidepressants (amitriptyline, imipramine)
	Voriconazole
CYP2B6	Efavirenz
	Methadone
Thiopurine *S*-methyltransferase	Thiopurines (azathioprine, mercaptopurine, thioguanine)
N-acetyltransferase	Hydralazine
	Isoniazid
Uridine diphosphate glucuronosyltransferase	Irinotecan

Cytochrome P450 Enzymes

About 57 different CYP isoenzymes have been documented to be present in humans, with 42 involved in the metabolism of exogenous xenobiotics and endogenous substances such as steroids and prostaglandins.[8] Isoenzymes within CYP families 1, 2, and 3 are known to be involved in the metabolism of medications, and significant interindividual variabilities in enzyme activity exist as a result of induction, inhibition, and genetic inheritance. The Pharmacogene Variation (PharmVar) Consortium (www.pharmvar.org) maintains a list of important pharmacogenes and their known alleles. Functional genetic polymorphism has been discovered for *CYP2D6*, *CYP2C19*, *CYP2C9*, *CYP2B6,* and *CYP3A4/5*, and their impacts on medication therapy are described hereunder.

CYP2D6

CYP2D6 is involved in the metabolism of numerous medications spanning a variety of therapeutic areas, including analgesics, antidepressants, antipsychotics, antiarrhythmics, antihypertensives, and anticancer agents, among others.[9] *CYP2D6* genetic variants are the best characterized among all of the *CYP* variants. The *CYP2D6* gene is one of the most polymorphic human genes; over 140 alleles have been identified. Each allele is assigned a function—normal function, decreased function, or no-function—depending on the effect of that allele on the resultant protein (see www.pharmvar.org for a complete list of alleles and their functions). In some individuals, the *CYP2D6* gene is deleted (as denoted by *CYP2D6**5*) or duplicated. This type of structural genetic variation, called copy number variation, can have a significant impact on CYP2D6 enzyme activity.

Translating *CYP2D6* genotype into phenotype uses an “activity score” system (Table e7-4)[10]. An “activity value” is assigned to each allele, based on its assigned function: 0 for no-function, 0.25 or 0.5 for decreased function, or 1 for normal function. If an allele is duplicated, then the activity value is multiplied by the number of copies present. An individual’s CYP2D6 activity score is the sum of the activity values for each of their alleles. For example, an individual with the *CYP2D6**1/*4* diplotype has one normal function allele (**1*, activity value = 1) and one no-function allele (**4*, activity value = 0) and thus would have an activity score of 1 + 0 = 1. An activity score of 1 corresponds to the IM phenotype.

TABLE e7-4

Phenotype Definitions Based on *CYP2D6, CYP2C19,* and *CYP2C9* Genotypes

Gene	Phenotype	Definition Based on Genotype
CYP2D6	Poor metabolizer	Activity score[a] = 0 (eg, two no-function alleles, such as **4/*5*)
	Intermediate metabolizer	Activity score[a]= $0 < x \le 1$ (eg, one normal function allele and one no-function allele, such as **1/*4*)
	Normal metabolizer	Activity Score[a] = $1 < x \le 2.25$ (eg, two normal function alleles, such as **1/*1*)
	Ultrarapid metabolizer	Activity score[a] > 2.25 (eg, more than two normal function alleles, such as **1/*2xN*)
CYP2C19	Poor metabolizer	Two no-function alleles (eg, **2/*2*)
	Likely poor metabolizer	One decreased function allele and one no-function allele (eg, **2/*9*)
	Intermediate metabolizer	One normal function allele and one no-function allele (eg, **1/*2*) or one increased function allele and one no-function allele (eg. **2/*17*)
	Likely intermediate metabolizer	One normal function allele and one decreased function allele (eg, **1/*9*) or one increased function allele and one decreased function allele (eg, **9/*17*) or two decreased function alleles (eg, **9/*9*)
	Normal metabolizer	Two normal function alleles (eg, **1/*1*)
	Rapid metabolizer	One normal function allele and one increased function allele *(*1/*17*)
	Ultrarapid metabolizer	Two increased function alleles (**17/*17*)
CYP2C9	Poor metabolizer	Activity score[a] = 0 (eg, two no-function alleles, such as **3/*3*)
	Intermediate metabolizer	Activity score[a] = 1 (eg, one normal function allele and one no-function allele, such as **1/*3* or two decreased function alleles, such as **2/*2*) or Activity Score[a] = 1.5 (eg, one normal function allele and one decreased function allele, such as **1/*2*)
	Normal metabolizer	Activity score[a] = 2 (two normal function alleles, such as **1/*1*)

[a] The activity score is the sum of the activity values for each allele in a diplotype.

The no-function variants, *CYP2D6*4* (c.1847G>A, defective splicing) and *CYP2D6*5* (gene deletion), are predominantly found in patients of European ancestry (5%-10% of the population are PMs) and result in an inactive enzyme and absence of enzyme, respectively. The predominant variants in people of Asian and African ancestry are *CYP2D6*10* (c.100C>T, Pro34Ser) and *CYP2D6*17* (c.1022C>T, Thr107Ile), respectively, both resulting in single-amino-acid substitution and consequent reduction in enzyme activity. The presence of two no-function alleles (eg, *CYP2D6*3, CYP2D6*4*, *CYP2D6*5*, or *CYP2D6*6*) results in the PM phenotype and the inability to metabolize CYP2D6-dependent substrates. Depending on the importance of the affected CYP2D6 pathway to overall drug metabolism and the drug's therapeutic index, clinically significant side effects may occur. A medication administered in its active form to a PM may result in elevated concentrations (Fig. e7-3, panel *A*). For example, the selective serotonin reuptake inhibitor paroxetine is primarily metabolized by CYP2D6 into inactive metabolites. A CYP2D6 PM who receives a normal dose of paroxetine will likely experience supratherapeutic plasma concentrations and be at higher risk for adverse effects. Per CPIC guidelines, these patients should receive 50% of the normal paroxetine dose or avoid the medication altogether.[11]

The therapeutic implication of *CYP2D6* polymorphism is different if the substrate is a prodrug (Fig. e7-3, panel *B*). In this case, PMs would not be able to convert the drug into the therapeutically active metabolite. Two examples of prodrugs dependent on CYP2D6-mediated conversion to active forms are codeine and tramadol. Codeine and tramadol are converted by CYP2D6 to morphine and *O*-desmethyltramadol, respectively, and CYP2D6 PMs experience little to no analgesic relief after taking these medications.[12] Similarly, lower efficacy of tamoxifen may be observed in PMs. Tamoxifen is converted by CYP2D6 to the more potent antiestrogen metabolite, endoxifen, and PMs have shortened time to recurrence of breast cancer and worse relapse-free survival.[13]

UMs possess higher than normal enzyme activity as a result of having more than two fully functional gene alleles. This phenotype has clinical implications in terms of dosage adjustment for some CYP2D6 substrates and risk for toxicity with other substrates. For the CYP2D6 substrate nortriptyline, which is inactivated by CYP2D6, patients with multiple copies of *CYP2D6*2* may require doses threefold to fivefold higher than normally recommended to achieve therapeutic plasma concentrations (50-150 ng/mL [mcg/L; 190-570 nmol/L]).[14] Similarly, lower efficacy may be observed in UMs with antiemetics such as ondansetron.[15] Conversely, UMs administered the usual therapeutic dose of codeine or tramadol might exhibit symptoms of narcotic overdose associated with high morphine or *O*-desmethyltramadol concentration, respectively. This toxicity potential had been observed in children who receive codeine or tramadol post-tonsillectomy and who are CYP2D6 UMs.[16,17] The FDA required a labeling change for codeine or tramadol contraindicating use of these medications to manage pain in children post-tonsillectomy because of the increased risk for respiratory depression in UMs. The American Academy of Pediatrics also cautioned against codeine use in children.[18] In April 2017, FDA contraindicated codeine use in all children younger than 12 years without regard to CYP2D6 status. FDA is considering amending this contraindication to include an exception for children who are known to be CYP2D6 NMs or IMs if they are not post-tonsillectomy as a result of a Citizen Petition submitted by an interdisciplinary group of pharmacogenomics experts.[19]

In general, drug interactions involving inhibition of CYP2D6 are relevant for UMs, NMs, and IMs, but not for PMs, who have no enzyme activity. For example, in NMs, but not PMs, hemodynamic responses to metoprolol (a CYP2D6 substrate) are pronounced and prolonged during concomitant diphenhydramine administration.[20] Strong CYP2D6 inhibitors, such as paroxetine, fluoxetine, and bupropion may substantially reduce the metabolic capacity of NMs so that they appear phenotypically as PMs.[21] This phenomenon is called *phenoconversion*. Moderate CYP2D6 inhibitors, such as duloxetine, may phenoconvert patients who are NMs based on genotype to IMs. Given the abundance and greater antiestrogenic activity of endoxifen,[13] the use of paroxetine, fluoxetine, or duloxetine in tamoxifen-treated patients should best be avoided. When there is a need for concurrent antidepressant administration with tamoxifen, those with a lesser extent of CYP2D6 inhibition, such as citalopram and venlafaxine,[21] would be better alternatives.

CYP2C19

Of over 35 alleles for the *CYP2C19* gene, the principal no-function alleles are *CYP2C19*2* (c.681G > A, aberrant splice site) in exon 5 and *CYP2C19*3* (c.636G > A, premature stop codon) in exon 4 of *CYP2C19*.[22] Individuals with two no-function alleles have no enzyme activity and are assigned the PM phenotype. IMs have a single no-function allele and reduced enzyme activity compared to NMs with two fully functional alleles (Table e7-4). The clinical relevance of *CYP2C19* genetic variation has been demonstrated for certain proton pump inhibitors (omeprazole, lansoprazole, pantoprazole, and dexlansoprazole), selective serotonin reuptake inhibitors (citalopram, escitalopram, and sertraline), tertiary amine tricyclic antidepressants (eg, amitriptyline), voriconazole, and clopidogrel.

CYP2C19 PMs exhibit up to a 10-fold increase in the area under the curve (AUC) of omeprazole compared with NMs.[23] The presence of a no-function

CYP2C19 allele has been associated with improved *Helicobacter pylori* cure rates after dual therapy including omeprazole,[24] and triple therapy including omeprazole, lansoprazole, or pantoprazole.[25,26] The cure rate achieved with dual therapy was 100% in PMs compared with 60% and 29% in IMs and NMs, respectively.[24]

These differences likely reflect the higher achievable intragastric pH in the PMs.[23] NMs who failed initial triple therapy (lansoprazole, clarithromycin, and amoxicillin) were retreated with high-dose lansoprazole (30 mg four times daily) and amoxicillin achieved a 97% *H. pylori* eradication.[23] A gene–dose effect in attainment of desirable intragastric pH ranges and *H. pylori* eradication rate, as well as the cost-effectiveness of pharmacogenomic-guided dosing is known for lansoprazole.[23,27] CPIC provides *CYP2C19* genotype-guided recommendations for proton pump inhibitors.[28]

Conversely, CYP2C19 IMs and PMs may have reduced response to the antiplatelet agent clopidogrel. This is because clopidogrel is a prodrug that requires conversion via CYP2C19 to its active form, as shown in Fig. e7-4. In IMs and PMs, clopidogrel may be less effective at inhibiting platelet aggregation and preventing cardiovascular events than in NMs, particularly in patients who suffer an acute coronary syndrome and undergo percutaneous coronary intervention (PCI).[29] In these patients, guidelines by CPIC recommend alternative therapy with prasugrel or ticagrelor for IMs and PMs in the absence of contraindications.[29] Patients who are genotyped as part of clinical care at the time of PCI exhibit a significantly lower risk of major adverse cardiovascular events in IMs and PMs treated with alternative therapy versus clopidogrel.[30] A large randomized controlled trial, the POPular Genetics trial (ClinicalTrials.gov Identifier NCT01761786), and a meta-analyses further support the value of *CYP2C19* genotyping to guide antiplatelet therapy.[31–33]

FIGURE e7-4

Clopidogrel bioactivation pathway. Approximately 85% of the drug is inactivated by esterases, and the remaining 15% is bioactivated to the active thiol metabolite that inhibits platelet activation via a two-step process. Cytochrome P450 (CYP) 2C19 is involved in both steps of the process.

The allelic variant *CYP2C19*17* is a promoter variant that leads to increased gene expression and increased overall CYP2C19 enzyme activity. Individuals with one normal function allele and one **17* allele are considered RMs (ie, *CYP2C19*1/*17*), whereas individuals with two **17* alleles are considered UMs (ie, *CYP2C19*17/*17*) (Table e7-4). CPIC guidelines recommend that CYP2C19 UMs receive higher doses of certain proton pump inhibitors and alternative therapy for other CYP2C19 substrates such as voriconazole, citalopram, and escitalopram.[11,28,34]

CYP2C9

Another polymorphic isoenzyme of CYP2C is CYP2C9, which metabolizes narrow therapeutic index drugs such as warfarin and phenytoin into inactive metabolites. Like *CYP2D6*, there is an activity score system to translate *CYP2C9* genotype into phenotype (Table e7-4). Warfarin is a racemic mixture, and the more potent *S*-isomer is metabolized by CYP2C9. *CYP2C9*2* (p.Arg144Cys; a decreased function allele) and *CYP2C9*3* (p. Ile359Leu; a no-function allele) are the two most common *CYP2C9* variants in patients of European ancestry, and both exhibit single-amino-acid substitutions at positions critical for enzyme activity.[35] This could have clinically important consequences in warfarin-treated patients. For example, a 90% reduction in *S*-warfarin clearance occurs in *CYP2C9*3* homozygotes compared with subjects homozygous for the wild-type (**1*) variant,[36] requiring dose reduction to 0.5 mg/day in a patient expressing the *CYP2C9*3* homozygote initially given usual doses of warfarin.[37] Patients requiring low doses of warfarin (less than or equal to 1.5 mg/day) have an overrepresentation of *CYP2C9* variant alleles and more difficulty with warfarin induction, requiring longer hospital stays to stabilize the warfarin regimen and experiencing a higher incidence of bleeding complications.[38] Similar to CYP2D6, concurrent medication therapy that affects CYP2C9 enzyme activity would influence the association between warfarin dose requirement and *CYP2C9* genotypes.[39]

Both *CYP2C9*2* and *CYP2C9*3* are more common in people of European ancestry than in those with Asian or African ancestry. The *CYP2C9*2* allele is rare to absent in people of Asian ancestry. The *CYP2C9*5*, **6*, **8*, and **11* alleles are decreased or no-function alleles occurring predominately in

African ancestry populations and leading to lower warfarin dose requirements.[35] The *CYP2C9*8* allele is most common among these, occurring in approximately 12% of people of African ancestry, and may have important implications for the metabolism of *CYP2C9* substrates in this population.

CYP2C9 polymorphisms, in conjunction with a polymorphism in the *VKORC1* gene (which encodes warfarin's target enzyme), influence warfarin dose requirements and form the basis for a consensus-based guideline from CPIC.[35] The use of *CYP2C9* and *VKORC1* genotypes in dosing warfarin is discussed in the "Polymorphisms in Drug Target Genes" section

CYP2B6

Although the role of CYP2B6 in the metabolism of anticancer medications such as cyclophosphamide and ifosfamide, the smoking cessation agent bupropion, and methadone has been studied, it is with the antiretroviral agents that its clinical relevance is most apparent.[40] The nonnucleoside reverse transcriptase inhibitor efavirenz is metabolized by CYP2B6 into inactive metabolites. Many patients receiving efavirenz experience central nervous system (CNS) adverse effects that are related to variable systemic exposure to the medication, which could be related to the lower metabolizing efficiency of the *CYP2B6*6*, **16*, or **18* alleles.[41] As such, dose reduction in patients with decreased CYP2B6 activity is recommended to minimize the risk of CNS adverse effects without compromising efficacy.[42]

CYP3A4/5

Within the *CYP3A* subfamily, at least three isoenzymes, namely, CYP3A4, CYP3A5, and CYP3A7, have been characterized. Despite as much as 40-fold interindividual variability in its expression, functional CYP3A4 is expressed in most adults, with intestinal expression playing a significant role in the first-pass metabolism of numerous medications. Although several *CYP3A4* variants (eg, **6*, **17*, and **20*) have been associated with decreased activity, their low frequency suggests limited clinical relevance.

CYP3A5 is polymorphically expressed in up to 60% of people of African ancestry and 33% of people of European ancestry, with *CYP3A5*3* (c.6986A>G, aberrant splice site) in intron 3 as the primary allele variant (no-function allele). In contrast to individuals with the *CYP3A5*1* allele, those with *CYP3A5*3* have no-functional CYP3A5 enzyme.[43] CYP3A4 and CYP3A5 mediate the metabolism of more than 50% of all clinically useful medications. However, with overlapping substrate specificities, it remains unknown whether some medications are substrates for *CYP3A5* but not *CYP3A4* and vice versa. Although variability exists between dose-adjusted concentration and *CYP3A5* genotypes, a correlation exists between trough concentrations of tacrolimus and *CYP3A5* genetic constitution. "Standard" dosing of tacrolimus is appropriate for CYP3A5 PMs (also known as "CYP3A5 nonexpressers"), common in patients of European ancestry. In contrast, patients of African ancestry who are likely to express the wild type (ie, **1*) *CYP3A5* allele (also known as "CYP3A5 expressers"), metabolize tacrolimus into inactive metabolites more quickly and thus may require higher starting doses to achieve therapeutic plasma concentrations. Genotyping for both *CYP3A5*3* and *CYP3A4*22,* a decreased function allele, is associated with improved dose prediction for tacrolimus.[44] CPIC guidelines providing pharmacogenomic-based dosing recommendations for tacrolimus are available.[43]

Phase II and Nucleotide-Base Metabolizing Enzymes

The clinical relevance of genetic polymorphisms pertaining to the thiopurine methyltransferase (TPMT), dihydropyrimidine dehydrogenase (DPD), and uridine diphosphate glucuronosyltransferase (UGT) enzymes has been demonstrated in the treatment of cancer. The *TPMT* gene has four primary no-function alleles: *TPMT*3A* (the most common), *TPMT*2*, *TPMT*3B*, and *TPMT*3C*. Thiopurine medications, such as 6-thioguanine, 6-mercaptopurine, and its precursor, azathioprine, are inactivated by TPMT, and patients who are homozygous or heterozygous for the *TPMT* variant alleles are at higher risk for developing serious hematological toxicities during treatment with the thiopurines.[45] TPMT represents one of the most successful examples of pharmacogenomic application of genotyping and phenotyping (eg, measuring enzyme activity). The most recent guideline is available through the CPIC.[45]

DPD mediates the metabolism of 5-fluorouracil and its precursor capecitabine. Patients with a no-function or decreased function allele of the *DPYD* gene encoding for the DPD enzyme cannot effectively metabolize 5-fluorouracil and thus may experience enhanced medication-related toxicities, including neutropenia, nausea, vomiting, severe diarrhea, stomatitis, mucositis, and hand-foot syndrome.[46] However, the usefulness and sensitivity of genotyping are related to which *DPYD* variants are included in individual test panels.

The camptothecin derivative irinotecan (CPT-11) is activated by carboxylesterase to SN-38, a potent topoisomerase I inhibitor. SN-38 is inactivated by glucuronidation via the polymorphic UGT1A1 enzyme, which may play a role in CPT-11-related toxicity. An extra thymine-adenine (TA) repeat within the TATA section of the *UGT1A1* promoter results in the *(TA)7TAA* allele (also known as *UGT1A1*28*), which possesses lower enzyme activity than the wild-type *(TA)6TAA* allele (ie, *UGT1A1*1*). Impaired SN-38 glucuronidation secondary to the *(TA)7TAA* allele may result in abnormally high SN-38 concentrations. More severe diarrhea and neutropenia are observed in irinotecan-treated patients who are homozygous or heterozygous carriers of the *(TA)7TAA* allele.[47] Moreover, a dose-related increase in the risk for severe neutropenia with irinotecan with the *UGT1A1 (TA)7TAA* allele is likely.[48] In 2005, the FDA approved the Invader® UGT1A1 Molecular Assay (Third Wave Technologies) to genotype for *UGT1A1* alleles, and the labeling for irinotecan was revised to recommend dose adjustment for individuals who are homozygous for the *(TA)7TAA* allele. Although the predictive value of *UGT1A1*28* polymorphism is confirmed in a meta-analysis, genetic testing is not a requirement by the regulatory agency.[49] The antiretroviral protease inhibitor atazanavir is an inhibitor of UGT1A1. Atazanavir can inhibit UGT1A1-mediated glucuronidation and elimination of bilirubin, which can lead to hyperbilirubinemia and jaundice. This effect is more pronounced in individuals with the *UGT1A1*28* allele, and CPIC guidelines recommend using alternative agents in homozygotes for the **28* allele.[50]

POLYMORPHISMS IN DRUG TRANSPORTER GENES

An example of a polymorphic drug transporter protein is OAT, a member of the solute carrier (SLC) transporter family. The *SLCO1B1* gene encodes for OAT polypeptide B1, which mediates the uptake of β-hydroxy-β-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors (statins) into the liver. Although statins effectively lower total and low-density lipoprotein cholesterol and reduce the risk for cardiovascular events in coronary heart disease, their use is associated with an increased risk for myopathy (muscle pain or weakness with elevated creatine kinase levels), particularly with higher statin doses or concomitant medications that increase statin bioavailability. Myopathy may rarely cause rhabdomyolysis, characterized by muscle breakdown and potentially leading to acute kidney injury. The reduced function *SLCO1B1* c.521T > C SNP, resulting in the p.Val174Ala substitution and contained within the *SLCO1B1*5* haplotype, has been associated with higher statin concentrations.[51] Each copy of the *C* allele increased the risk for myopathy with simvastatin 40 mg/day by ~2.5-fold in a genome-wide association study (GWAS).[52] The association between the 521C allele and statin-induced myopathy is now well established.

Similarly, the 521C allele is associated with an increased incidence of less severe yet troubling adverse effects that lead to statin discontinuation, including myalgias without significant creatine kinase elevation.[53] For example, there is a known risk for myopathy in patients expressing the 521T>C allele and receiving simvastatin. Hence, lower simvastatin doses or alternative statin drugs should be used in 521C carriers. CPIC guidelines support this strategy.[51]

POLYMORPHISMS IN DRUG TARGET GENES

② Genetic polymorphisms occur commonly for drug target proteins, including receptors, enzymes, and ion channels. Drug target genes may work in concert with genes that affect pharmacokinetic properties (ie, genes for drug-metabolizing enzymes and transporters) to contribute to overall medication response. For example, the genes for *CYP2C9*, the major metabolizing enzyme for *S*-warfarin, and vitamin K oxidoreductase (VKOR), the target enzyme for warfarin, together influence warfarin dose response, as shown in Fig. e7-5. The following section highlights some of the drug target protein genes known to influence the efficacy, safety, or optimal dosage of various pharmacologic agents.

FIGURE e7-5

Proteins involved in warfarin pharmacokinetics and pharmacodynamics. Warfarin inhibits VKOR, thus preventing the formation of reduced vitamin K_1, which is a necessary cofactor for γ-carboxylation and activation of clotting factors II, VII, IX, X, and proteins C and S. (CYP2C9, cytochrome P450 2C9; F, clotting factor; PROC, protein C; PROS, protein S; VKOR, vitamin K oxidoreductase.)

Receptor Genotypes and Medication Response

The β_1-adrenergic receptor gene (*ADRB1*) has been a major focus of research into genetic determinants of responses to β-adrenergic receptor antagonists in cardiovascular disease and heart failure. β_1-Receptors are located in the heart and kidney, where they are involved in the regulation of heart rate, cardiac contractility, and blood pressure. There are two common nonsynonymous SNPs in the *ADRB1* at codons 49 (p.Ser49Gly) and 389 (p.Arg389Gly). The Ser49Gly and Arg389Gly SNPs are in strong linkage disequilibrium. The Ser49-Arg389 haplotype is associated with an increased risk for death among patients with coronary heart disease. The *ADRB1* Ser49Gly and Arg389Gly SNPs also appear to modulate blood pressure and clinical responses to β_1-receptor blockade. Specifically, hypertensive patients who were homozygous for the Ser49-Arg389 haplotype were found to have greater blood pressure reductions with metoprolol, compared with carriers of the Gly49 and/or Gly389 alleles.[54] In patients with coronary heart disease, atenolol treatment abolishes the increased risk for mortality associated with the Ser49-Arg389 haplotype. Among patients with heart failure, the Arg/Arg389 genotype was associated with greater improvements in left ventricular ejection fraction with carvedilol and metoprolol treatment and greater survival benefits with bucindolol, an agent not approved for use in the United States. CPIC guidelines addressing the use of *ADRB1* genotype in β-blocker prescribing are forthcoming.

The mu-opioid receptor gene (*OPRM1*) codes for the target protein of opioid analgesics, including codeine and tramadol. Although a common polymorphism, A118G, results in lower protein expression, its contribution to individual differences in opioid response is unclear.[12,55] As such, the evidence associated with the *OPRM1* gene is ranked as CPIC level C, meaning that no prescribing action is recommended based on genotype results. Nonetheless, the A118G polymorphism is included on some commercial pharmacogenomic testing panels.

Enzyme Genes and Medication Response

Vitamin K oxidoreductase (VKOR) is an example of an enzyme with genetic contributions to medication response. Warfarin exerts its anticoagulant effects by inhibiting VKOR and thus preventing carboxylation of the vitamin K-dependent clotting factors II, VII, IX, and X, as shown in Fig. e7-5. *VKORC1* encodes for the warfarin-sensitive component of VKOR. Variants in the *VKORC1* coding region cause rare cases of warfarin resistance, with carriers of these mutations requiring either exceptionally high warfarin doses (more than 100 mg/week) to achieve effective anticoagulation or failing to respond to warfarin at any dose.[35]

Aside from rare cases of warfarin resistance, there is substantial variability among patients in the dose of warfarin necessary to produce optimal anticoagulation, defined as an international normalized ratio of 2 to 3 for most indications. A common SNP in the *VKORC1* regulatory region, c.-1639G>A, significantly contributes to the interpatient variability in warfarin response, as it modulates *VKORC1* gene expression. Specifically, the –1639 AA, AG, and GG genotypes lead to high, intermediate, and low sensitivity to warfarin, respectively. Corresponding warfarin dose requirements are approximately 3 mg/day with the AA genotype, 5 mg/day with the AG genotype, and 6 to 7 mg/day with the GG genotype. *VKORC1* genotype, together with *CYP2C9* genotype, explains approximately 30% of the interpatient variability in warfarin dose requirements.[35] Clinical characteristics (eg, age, body size) and vitamin K intake contribute to additional dose variability.

Warfarin dose requirements vary by ancestry, with higher dose requirements among individuals of African ancestry and lower requirements among patients of Asian ancestry compared with patients of European ancestry. This variability is largely explained by differences in *VKORC1* genotype frequency. Specifically, the low-dose AA genotype is most common in patients of Asian ancestry, and the high-dose GG genotype is most common in patients of African ancestry, whereas the intermediate-dose AG genotype is most common in persons of European ancestry.

Warfarin-dosing algorithms that incorporate *CYP2C9* and *VKORC1* genotypes and clinical (eg, age, weight, interacting medications) factors are publicly available to assist with warfarin dosing (eg, www.warfarindosing.org). In addition, the FDA-approved labeling for warfarin contains a dosing table based on *CYP2C9* and *VKORC1* genotypes (Table e7-5). Among people of predominately European ancestry, greater time in the therapeutic INR range and a reduction in the composite endpoint of major bleeding, venous thromboembolism, INR ≥4, and death following hip or knee arthroplasty were observed with genotype-guided compared to standard warfarin dosing.[56,57] Importantly, when limiting *CYP2C9* genotyping to the **2* and **3* alleles, dosing using a pharmacogenomic algorithm may lead to overestimation of warfarin dose requirements in individuals of African ancestry.[58] Thus, it is important to genotype for *CYP2C9* variants that occur commonly in people of African ancestry (eg, **5, *6, *8*, and **11*), as highlighted in CPIC guidelines.[35]

TABLE e7-5

Initial Warfarin Dose Recommendations (in mg/day) Provided in the FDA-Approved Warfarin Labeling According to *CYP2C9* and *VKORC1* Genotypes

	CYP2C9					
VKORC1	**1/*1*	**1/*2*	**1/*3*	**2/*2*	**2/*3*	**3/*3*
AA	3-4	3-4	0.5-2	0.5-2	0.5-2	0.5-2
AG	5-7	3-4	3-4	3-4	0.5-2	0.5-2
GG	5-7	5-7	3-4	3-4	3-4	0.5-2

IMMUNE-RELATED GENES

② The human leukocyte antigen (*HLA*) genes are among the most polymorphic in the human genome. These genes encode for proteins that recognize "self" from "non-self" and play a key role in the function of the immune system. The presence of certain *HLA* alleles has been linked to serious, potentially life-threatening adverse skin reactions with carbamazepine and phenytoin, commonly prescribed antiepileptic agents.[59,60] Stevens–Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) are hypersensitivity reactions characterized by blistering, mucosal erosions, and epidermal detachment. TEN is associated with more extensive skin involvement and a mortality rate approaching 25%.

Individuals with southeastern Asian ancestry (ie, southern China, Thailand, Malaysia, Indonesia, Taiwan, and Philippines) have a twofold to threefold higher prevalence of carbamazepine- or phenytoin-induced SJS and TEN than individuals of Japanese, Korean, or European ancestry. The human leukocyte antigen type B (*HLA-B*) **15:02* allele also occurs at a higher prevalence in individuals of southeastern Asian ancestry and has been highly correlated with risk for medication-induced SJS and TEN. Individuals of South Asian descent, including India, have an intermediate prevalence of this allele (2%-4%). It occurs in less than 1% of those with Japanese and Korean ancestry and is largely absent in others.

While the mechanism by which the *HLA-B*15:02* allele increases the risk for these toxic cutaneous reactions is unclear, it may involve activation and proliferation of T lymphocytes on carbamazepine exposure. The FDA-approved carbamazepine labeling recommends *HLA-B*15:02* screening in individuals with ancestry from southern Asia prior to carbamazepine use (see Table e7-6). Carbamazepine should be avoided in patients testing positive for the *HLA-B*15:02* allele.[59] Moreover, because of potential for phenytoin-induced SJS in the presence of the *HLA-B*1502* allele, phenytoin should also be avoided in individuals with the *HLA-B*15:02* allele.[60] In addition, the *HLA-B*31:01* allele is associated with risk of serious cutaneous reactions during carbamazepine treatment and is addressed in updated CPIC guidelines.[59] Allopurinol, a commonly-used treatment for hyperuricemia and gout, is also associated with severe cutaneous adverse reactions in the presence of a specific *HLA* allele, namely *HLA-B*58:01*. Allopurinol is contraindicated in patients who carry the *HLA-B*58:01* allele.[61]

TABLE e7-6

Examples of Drugs and Corresponding Pharmacogenomic Information in Their FDA-Approved Labels

Drug(s)	Gene(s)	Content
Abacavir	*HLA-B*	The *HLA-B*57:01* allele increases the risk for abacavir hypersensitivity. Genotype screening is recommended prior to abacavir use. Abacavir should be avoided in patients with the *HLA-B*57:01* allele, unless the potential benefit of abacavir clearly outweighs the risk.
Atomoxetine	*CYP2D6*	*CYP2D6* PMs may have 10-fold increased atomoxetine exposure compared with extensive metabolizers. In CYP2D6 PMs, a starting dose of 0.5 mg/kg/day is recommended in children and adolescents < 70 kg and only increased to the usual target dose of 1.2 mg/kg/day if symptoms fail to improve after 4 weeks and the initial dose is well tolerated.
Azathioprine, 6-mercaptopurine, thioguanine	*TPMT*	Patients with a no-function *TPMT* allele are at increased risk for serious, potentially life-threatening myelosuppression if given conventional doses of thiopurine. Consideration of either *TPMT* genotyping or phenotyping recommended, with dose reduction in patients with a reduced activity genotype or phenotype.
5-Fluorouracil, capecitabine	*DPYD*	Dihydropyrimidine dehydrogenase (DPD) deficiency may rarely lead to severe toxicity (eg, diarrhea, neutropenia, neurotoxicity) with 5-fluorouracil and capecitabine. 5-fluorouracil and capecitabine should be avoided in patients with DPD deficiency.
Carbamazepine	*HLA-B*	The *HLA-B*15:02* allele increases the risk for serious and potentially fatal dermatologic reactions (eg, Stevens–Johnson syndrome and toxic epidermal necrolysis) with carbamazepine. At-risk populations include those from southeast Asia who should be screened for the *HLA-B*15:02* allele prior to starting carbamazepine. Carbamazepine should be avoided in *HLA-B*15:02* positive patients unless the potential benefit clearly outweighs the risks.
Celecoxib	*CYP2C9*	Celecoxib clearance is reduced in carriers of the *CYP2C9*3* allele. Celecoxib should be administered with caution and at lower doses in patients with the *CYP2C9*3* allele.
Cetuximab, panitumumab	*EGFR*	Cetuximab and panitumumab inhibit the epidermal growth factor receptor (EGFR). Candidates for these agents should have immunohistochemical evidence of EGFR expression.
	KRAS mutations	KRAS is a G protein in the EGFR pathway. Patients with a *KRAS* mutation in codon 12 or 13 may not derive any benefit from cetuximab or panitumumab, and use of these drugs is not recommended.
Clopidogrel	*CYP2C19*	*CYP2C19* is involved in the biotransformation of clopidogrel to its active form. Individuals with the *CYP2C19* PM phenotype secondary to genetic polymorphism may fail to derive sufficient protection against adverse cardiovascular events with clopidogrel. These risks are particularly high in patients who undergo coronary artery stent placement.
Codeine	*CYP2D6*	CYP2D6 metabolizes codeine into morphine. Respiratory depression and death have occurred in children who received codeine following tonsillectomy and/or adenoidectomy and had evidence of being CYP2D6 ultrarapid metabolizers. Codeine is contraindicated in children younger than 12 years and in children younger than 18 years following tonsillectomy and/or adenoidectomy.
Irinotecan	*UGT1A1*	The *UGT1A1*28* allele is associated with increased risk for irinotecan-induced neutropenia, with homozygotes having the highest risk. Lower irinotecan starting doses are indicated in patients known to be homozygous for the *UGT1A1*28* allele.

Lenalidomide	Chromosome *5q* deletion	Myelodysplastic syndromes with the chromosome 5q deletion are associated with an increased risk of hematologic toxicity with lenalidomide. More frequent monitoring of complete blood counts is recommended during lenalidomide initiation in patients with the chromosome 5q deletion. Consider lenalidomide dose reduction or interruption and use of blood products and/or growth factors if CBC alterations are detected.
Primaquine	*G6PD*	Genetic variation leading to *G6PD* deficiency increases the risk for primaquine-induced hemolytic anemia. Obtaining a *G6PD* enzyme activity level prior to primaquine use is recommended for patients of African or Mediterranean ancestry, who are at higher risk of *G6PD* deficiency, with the use of lower doses in patients who have a deficient level.
Rasburicase	*G6PD*	Genetic variation leading to *G6PD* deficiency increases the risk for rasburicase-induced hemolytic anemia. Obtaining a *G6PD* enzyme activity level prior to rasburicase use is recommended in patients of African or Mediterranean ancestry, who are at higher risk of *G6PD* deficiency. Rasburicase should be avoided in individuals with a *G6PD* deficiency.
Tramadol	*CYP2D6*	CYP2D6 metabolizes tramadol into its more potent active metabolite, O-desmethyltramadol. Life-threatening respiratory depression and death have occurred in children who received tramadol. Some of the reported cases followed tonsillectomy and/or adenoidectomy; in at least one case, the child was a CYP2D6 ultrarapid metabolizer. Tramadol is contraindicated in children younger than 12 years and in children younger than 18 years following tonsillectomy and/or adenoidectomy.
Trastuzumab	*HER2*	Decreased tumor progression in breast cancer with trastuzumab has only been demonstrated when *HER2* is overexpressed. Overexpression of *HER2* should be confirmed by protein overexpression or gene amplification prior to trastuzumab initiation.
Voriconazole	*CYP2C19*	Patients with the IM or PM phenotype have twofold to fourfold higher voriconazole exposure, respectively. However, no recommendations are made in the FDA label for genetic screening or dose adjustment.
Warfarin	*CYP2C9*, *VKORC1*	The *CYP2C9*2* and **3* alleles are associated with reduced warfarin metabolism and increased bleeding risk, while the *VKORC1-1639A* allele is associated with increased warfarin sensitivity. Lower doses of warfarin should be started in patients known to have decreased or no-function *CYP2C9* or *VKORC1* alleles. However, genetic testing is not mandated.

CBC, complete blood count; CXCR4, chemokine-related receptor; EGFR, epidermal growth factor receptor; G6PD, glucose-6-phosphate dehydrogenase; HIV, human immunodeficiency virus; HLA, human leukocyte antigen; IM, intermediate metabolizer; PM, poor metabolizer

Data from https://www.fda.gov/drugs/science-and-research-drugs/table-pharmacogenomic-biomarkers-drug-labeling. Accessed January 12, 2022.

The use of abacavir, a nucleoside reverse transcriptase inhibitor of HIV-1, causes a severe, and occasionally fatal, hypersensitivity reaction in some patients. The abacavir hypersensitivity reaction (AHR) is strongly associated with the presence of another allelic variant of the *HLA* gene, *HLA B*57:01*. Screening for *HLA B*57:01* with avoidance of abacavir in patients testing positive for the allele reduces AHR incidence.[62] The screening recommendation has been incorporated into abacavir product labeling as well as treatment guidelines.[62]

NEW GENETIC TARGETS AND THERAPEUTIC INTERVENTIONS

The discovery of genes that confer disease has led to an improved understanding of the molecular mechanisms involved in disease pathophysiology. Once associations between genes and diseases are discovered, scientists can elucidate the functions of the encoded proteins and more clearly define the consequences of genetic mutations. Insight into the genetic control of cellular functions may reveal new strategies for disease treatment and prevention.

Targeted Therapies for Cancer. Cancer is a disease of the genome, with genetic mutations driving uncontrolled cell growth and division. Knowledge of the molecular mechanisms behind cancer growth can lead to the development of targeted therapies. For example, overexpression of the human epidermal growth factor receptor 2 (HER2, also known as Her2/neu and ErbB2), secondary to *HER2* gene amplification occurs in 20% of metastatic breast cancers and is associated with more aggressive cancer and decreased survival.[63] The discovery of *HER2* overexpression and its effects on cancer prognosis led to the development of trastuzumab, a recombinant monoclonal antibody that targets HER2 and blocks HER2-stimulated growth and survival of cancer cells. The addition of trastuzumab to breast cancer chemotherapy slows the progression of cancer and improves tumor response rates in women with HER2-positive tumors.[63] Testing for *HER2* overexpression is necessary to determine which patients may benefit from trastuzumab. The FDA has approved several tests that detect *HER2* overexpression either directly by measuring the amount of protein or indirectly by measuring gene amplification.

Similarly, overexpression of the epidermal growth factor receptor (EGFR, also known as HER1 or ErbB1) in head and neck, colon, and rectal cancer is associated with cancer growth and a poor clinical prognosis. Cetuximab and panitumumab are recombinant monoclonal antibodies that block activation of the EGFR. Both improve survival in metastatic colorectal cancer that overexpresses EGFR and are thus indicated in this setting.[64,65] Erlotinib and gefitinib inhibit the intracellular phosphorylation of tyrosine kinase associated with the EGFR and are indicated in non-small cell lung cancer. Other examples of targeted chemotherapy developed based on genetic abnormalities include rituximab, a monoclonal antibody used to treat CD20-positive, B-cell non-Hodgkin's lymphoma and chronic lymphocytic leukemia; imatinib, dasatinib, and nilotinib, kinase inhibitors that block the product of a reciprocal translocation between chromosomes 9 and 22 in chronic myeloid leukemia (CML); and crizotinib, an anaplastic lymphoma kinase (ALK) and c-ros oncogene 1, receptor tyrosine kinase (ROS-1) inhibitor that targets the *EML4-ALK* gene fusion product in non-small cell lung cancer.

Targeted Therapy for Cystic Fibrosis. Cystic fibrosis is caused by genetic mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) protein, which is expressed in the airways, intestines, pancreas, bile duct, and sweat glands. In these locations, the CFTR protein serves a critical role in the regulation of fluid and ion transport. The CFTR is composed of two nucleotide-binding domains and two transmembrane domains. The transmembrane domain forms a chloride channel, while the nucleotide-binding domain acts as a gate to regulate chloride transport across the cell membrane. Mutations in the *CFTR* gene lead to altered fluid and ion transport and disrupt mucus clearance in the airways and intestinal tract resulting in airway obstruction and digestive problems.

Mutations in the *CFTR* gene affect protein synthesis, processing, regulation, or ion conductance. Ivacaftor was approved by the FDA in 2012 as the first medication to target defects in the CFTR.[66] Ivacaftor was initially approved for the treatment of cystic fibrosis in children who have the Gly551Asp mutation, which occurs in about 4% of patients with cystic fibrosis and causes defects in chloride transport through the ion channel. Ivacaftor potentiates chloride ion flow and results in rapid and sustained improvement in lung function in patients with cystic fibrosis. The labeling for ivacaftor has been updated to include additional variants that are also responsive to ivacaftor potentiation. Additional targeted therapies for cystic fibrosis have come to market that collectively impact 90% of the cystic fibrosis patient population. These agents, including lumacaftor/ivacaftor, tezacaftor/ivacaftor, and elexacaftor/tezacaftor/ivacaftor, have the potential to improve the quality and length of life of these patients, as they all target the underlying cause of cystic fibrosis. In particular, they are relevant for patients who have at least one (elexacaftor/tezacaftor/ivacaftor) or two copies (lumacaftor/ivacaftor, tezacaftor/ivacaftor) of the F508del mutation, the most common mutation implicated in cystic fibrosis. Presence of this mutation prevents the proper folding and trafficking of the CFTR protein to the cell membrane, and lumacaftor, tezacaftor, and elexacaftor work to correct this issue.

PHARMACOGENOMIC MEDICATION LABELING AND GUIDELINES

⑦ More than 250 medications now contain pharmacogenomic information in their FDA-approved labeling.[67] Examples of these are shown in Table e7-6. Note that not all of the pharmacogenomic information in FDA labels is considered clinically actionable (ie, associated with a specific medication or dosage recommendation). Pharmacogenomic information appears in various sections of the label. For example, the information appears as a Boxed Warning for clopidogrel and carbamazepine because of the serious consequences of genetic variation on medication response. However, for warfarin, mercaptopurine, and irinotecan, the pharmacogenomic information appears in the medication dosing section. The FDA maintains a table of pharmacogenomic biomarkers in medication labels (https://www.fda.gov/drugs/science-and-research-drugs/table-pharmacogenomic-biomarkers-drug-labeling) as well as tables of pharmacogenetic associations supporting therapeutic management recommendations, potential impact on safety or response, and potential impact on pharmacokinetic properties only (https://www.fda.gov/medical-devices/precision-medicine/table-pharmacogenetic-associations).[67,68] Other regulatory agencies worldwide (eg, the European Medicines Agency) also include pharmacogenomic information on medication labeling. This information is curated through the Pharmacogenomics Knowledgebase (PharmGKB; www.pharmgkb.org), which is a searchable database of pharmacogenomics literature and guidelines.

Guidelines are available to assist with translating genotype results into actionable prescribing decisions for many medications. Among these are guidelines from CPIC (https://cpicpgx.org/) and the Dutch Pharmacogenetics Working Group (DPWG).[69,70] These consortia do not recommend whether genetic tests should be ordered, but rather, how to use existing genetic information.

Genes and drugs/drug classes with CPIC guidelines published as of 2021 are listed in Table e7-7. The CPIC guidelines, DPWG guidelines, in addition to other pharmacogenomic information, are freely available through PharmGKB and/or CPIC websites. A list of these and other key pharmacogenomics resources are listed in Table e7-8.

TABLE e7-7

Examples of Drugs/Drug Classes and Genes with Available Guidelines from the Clinical Pharmacogenetics Implementation Consortium

Drugs/Drug Classes	Genes
Abacavir	*HLA-B*
Allopurinol	*HLA-B*
Aminoglycosides	*MT-RNR1*
Atazanavir	*UGT1A1*
Atomoxetine	*CYP2D6*
Carbamazepine	*HLA-A, HLA-B*
Clopidogrel	*CYP2C19*
Efavirenz	*CYP2B6*
Fluoropyrimidines	*DPYD*
Ivacaftor	*CFTR*
Non-steroidal anti-inflammatory drugs	*CYP2C9*
Ondansetron	*CYP2D6*
Opioids	*CYP2D6, OPRM1, COMT*
Oxcarbazepine	*HLA-B*
Peginterferon-alpha-based regimens	*IFNL3*
Phenytoin	*CYP2C9, HLA-B*
Proton pump inhibitors	*CYP2C19*

Rasburicase	*G6PD*
Selective serotonin reuptake inhibitors	*CYP2D6, CYP2C19*
Simvastatin	*SLCO1B1*
Succinylcholine	*RYR1, CACNA1S*
Tacrolimus	*CYP3A5*
Tamoxifen	*CYP2D6*
Thiopurines	*TPMT, NUDT15*
Tricyclic antidepressants	*CYP2D6, CYP2C19*
Volatile anesthetic agents	*RYR1, CACNA1S*
Voriconazole	*CYP2C19*
Warfarin	*CYP2C9, CYP4F2, VKORC1*

Pharmacogenomics Resources

Resource	Description	Website
Clinical Pharmacogenetics Implementation Consortium (CPIC)	Creates gene/drug pair guidelines that provide guidance on how to use existing pharmacogenomic test results to optimize medication therapy	www.cpicpgx.org
Dutch Pharmacogenetics Working Group (DPWG)	Creates gene/drug pair guidelines that provide guidance on how to use existing pharmacogenomic test results to optimize medication therapy	Available through www.pharmgkb.org
FDA Table of Pharmacogenetic Associations	List of gene/drug associations that the FDA has evaluated and believes there is sufficient scientific evidence to support. List is continually being evaluated and updated with input from the pharmacogenomics community.	www.fda.gov/medical-devices/precision-medicine/table-pharmacogenetic-associations
FDA Table of Pharmacogenomic Biomarkers	Contains a list of drugs with pharmacogenomic information in their FDA-approved labeling	www.fda.gov/drugs/science-research-drugs/table-pharmacogenomic-biomarkers-drug-labeling
Genetic Testing Registry (GTR)	Centralized database of genetic testing labs worldwide and their test offerings created via voluntary submissions	www.ncbi.nlm.nih.gov/gtr/
Pharmacogenomics Knowledgebase (PharmGKB)	Searchable database of curated pharmacogenomic literature and information, including clinical guidelines and drug labeling from around the world. Also includes important pharmacogene summaries and pharmacogenomic pathway diagrams	www.pharmgkb.org
Pharmacogene Variation Consortium (PharmVar)	Online repository for pharmacogene nomenclature. Publishes “GeneFocus” papers that summarize key information about important pharmacogenes.	www.pharmvar.org

ETHICAL CONSIDERATIONS

Traditionally, *genetic testing* refers to screening human genetic material to identify genotypes associated with disease susceptibility or carrier status for heritable diseases, such as Huntington’s disease or breast cancer. This kind of testing can have serious ethical and social implications. For example, knowledge that a patient is at risk for developing a genetic disorder could result in emotional distress for the individual at risk and his or her family members and the fear of discrimination by employers or insurance companies.

Within the context of pharmacogenomics, however, testing involves searching for genetic variations linked to medication efficacy or toxicity rather than to disease susceptibility. In many instances, this form of testing will carry little risk for ethical, legal, and social concerns. For example, knowledge that a person has a genotype associated with a poor response to clopidogrel may be of little consequence because there are alternative therapies available. However, more serious implications may arise if a person is predicted to respond poorly to a medication based on genotype, and treatment options are limited. The federal Genetic Information Nondiscrimination Act (GINA) of 2008 prohibits health insurance providers and employers from discriminating against an individual based on genetic information. However, GINA does not protect against discrimination related to disability, life, and long-term care insurance. In addition, it does not apply to employers with fewer than 15 employees.

ROLE OF CLINICIANS

⑧ Pharmacogenomics provides opportunities to improve medication outcomes but requires that clinicians be knowledgeable about genetic determinants of medication response and how to translate genetic information into prescribing decisions. Importantly, genetic information needs to be considered in the context of important clinical factors, such as age, body size, organ function, and concomitant medication therapy.

Pharmacists are broadly trained in a number of medication-related areas, including pharmacology, pharmacokinetics, and pharmacodynamics. This places pharmacists in a unique position in dealing with the complexities of pharmacotherapy in the era of pharmacogenomics. Pharmacists can take a leadership role on multidisciplinary teams charged with interpreting genetic test results and choosing the most appropriate medication for a given patient based on genotype, and in counseling patients about the clinical implications of their results.[71,72] Furthermore, it is becoming more common for patients to obtain their pharmacogenomic test results, either from clinical services, large-scale research projects (eg, *All of Us* Research Program), or direct-to-consumer testing.[73,74] Thus, it will be essential for clinicians to stay abreast of important pharmacogenomic discoveries and guideline updates. Genomics competencies for healthcare professionals are available via the Genetics/Genomics Competency Center (https://genomicseducation.net/).

In addition, pharmacists can form partnerships with other healthcare professionals in the provision of clinical pharmacogenomics services. For example, some pharmacists are working together with genetic counselors in pharmacogenomics. Genetic counselors have specific training in communicating complex health-related genetic information to patients and can explain secondary (ie, disease-associated) findings from pharmacogenomic testing (eg, *UGT1A1*28/*28* and Gilbert syndrome), whereas the pharmacist can provide genotype-guided medication recommendations to maximize medication efficacy and safety. Others who may be involved with pharmacogenomics implementation include informatics personnel for integrating results into electronic health records with clinical decision support (eg, drug-gene interaction alerts), and clinical pathologists who can establish genotyping methodology when performed in-house. Some clinicians pursue post-graduate residency or fellowship training in pharmacogenomics. These individuals often lead the implementation of pharmacogenomics in health systems, develop new clinical pharmacogenomics services, and/or engage in pharmacogenomics research and educational efforts.

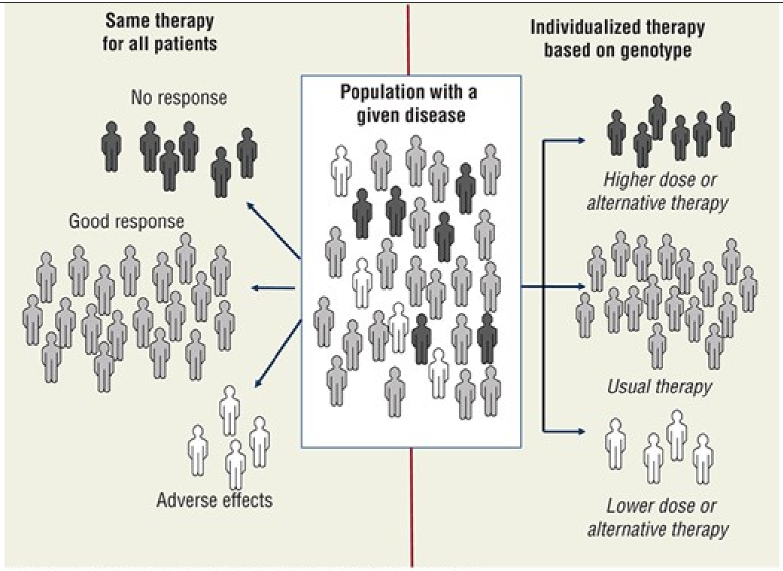
APPLICATION OF PHARMACOGENOMICS TO MEDICATION MANAGEMENT

Pharmacogenomics has the potential to greatly improve medication use and therapy outcomes when applied across the Patient Care Process.[75] Clinicians may be able to predict the likelihood that an individual will respond to a particular medication based on the patient's genotype. Medications may be avoided or prescribed in lower doses with careful monitoring in patients genetically predisposed to their adverse effects. This would be of particular benefit for narrow therapeutic index drugs. For example, warfarin may be initiated at lower doses with closer monitoring in patients with a *VKORC1* genotype associated with increased warfarin sensitivity or a *CYP2C9* allele associated with reduced warfarin metabolism.

With pharmacogenomics, it also may be possible to eliminate the trial-and-error approach to medication prescribing for many diseases. Instead, clinicians may be able to use genetic information to match the right medication to the right patient at the right dose while minimizing adverse effects. For example, the current approach to depression management involves the trial of various antidepressants until symptom remission is achieved with acceptable medication tolerability. Commonly, the initial agent(s) fails to control depressive symptoms or produces intolerable adverse effects (Fig. e7-6). Trials of additional or alternative antidepressants must be undertaken until treatment is deemed successful. In the interim, the patient remains depressed, which has significant implications for the patient's quality of life, work productivity, and potentially, risk for suicide. With pharmacogenomics, clinicians may be able to choose the antidepressant medication expected to provide the greatest response with the best tolerability for a particular patient based on his or her DNA.

FIGURE e7-6

Traditional and individualized approaches to pharmacologic management of disease.



Same therapy for all patients
Individualized therapy based on genotype
No response
Population with a given disease
Higher dose or alternative therapy
Good response
Usual therapy
Adverse effects
Lower dose or alternative therapy

New medications may be developed based on knowledge about genetic control of cellular functions. For example, the discovery that CML was caused by chromosome translocation and consequent production of an enzyme capable of producing life-threatening lymphocyte levels led to accelerated FDA approval of imatinib, an inhibitor of the translocation-created enzyme, for treatment of CML. In addition, future medication development may focus on treating specific genetic subgroups instead of broadly treating all individuals with a particular disease. Along these lines, the FDA is encouraging pharmaceutical companies to submit pharmacogenomic data during the medication development process. Ultimately, pharmacogenomics may improve the quality and reduce the costs of healthcare by decreasing treatment failures and adverse medication reactions, and by leading to the discovery of new genetic targets and therapeutic interventions for disease management.

ABBREVIATIONS

A	adenine
ADRB1	β_1-adrenergic receptor gene
AHR	abacavir hypersensitivity reaction
ALK	anaplastic lymphoma kinase
AUC	area under the curve
C	cytosine
CFTR	cystic fibrosis transmembrane conductance regulator
CML	chronic myeloid leukemia
CNS	central nervous system
CPIC	Clinical Pharmacogenetics Implementation Consortium
CYP	cytochrome P450

dbSNP	National Center for Biotechnology Information SNP database
DPD	dihydropyrimidine dehydrogenase
EGFR	epidermal growth factor receptor
ENCODE	ENCyclopedia of DNA Elements
FDA	Food and Drug Administration
G	guanine
G6PD	glucose-6-phosphate dehydrogenase
GINA	Genetic Information Nondiscrimination Act
GWAS	genome-wide association study
HER2	human epidermal growth factor receptor 2
HIV	human immunodeficiency virus
HLA	human leukocyte antigen
HMG-CoA	β-hydroxy-β-methylglutaryl-coenzyme A
IM	intermediate metabolizer
NIH	National Institutes of Health
NM	normal metabolizer
OAT	organic anion transporter
PGRN	Pharmacogenomics Research Network
PharmGKB	Pharmacogenomics Knowledgebase
PM	poor metabolizer
RM	rapid metabolizer
SJS	Stevens–Johnson syndrome
SLC	solute carrier
SNP	single nucleotide polymorphism
SSRI	selective serotonin reuptake inhibitor
T	thymine

TA	thymine-adenine
TEN	toxic epidermal necrolysis
TPMT	thiopurine *S*-methyltransferase
UGT	uridine diphosphate glucuronosyltransferase
UM	ultrarapid metabolizer
VKOR	vitamin K oxidoreductase

SELF-ASSESSMENT QUESTIONS

1. The site(s) for genetic variations that may affect drug pharmacodynamics include:

    A. Drug-metabolizing enzymes

    B. Drug target proteins

    C. Drug transporter proteins

    D. A and B

2. The most commonly occurring variant in the human genome is:

    A. Single nucleotide polymorphism

    B. Tandem repeat polymorphism

   C. Nucleotide base deletion

   D. Nucleotide base insertion

3. *CYP2D6* polymorphism can affect:

   A. Drug toxicity

   B. Drug interaction potential

   C. Drug delivery

   D. A and B

4. Which CYP2D6 phenotype is associated with the least analgesic response to codeine?

   A. Ultrarapid metabolizer

   B. Normal metabolizer

   C. Intermediate metabolizer

   D. Poor metabolizer

5. Which of the following is an example of a drug target gene?

   A. *TPMT*

   B. *SLCO1B1*

   C. *CYP2C19*

   D. *VKORC1*

6. Which gene is predictive of clopidogrel effectiveness?

   A. *CYP2C9*

   B. *CYP2C19*

   C. *CYP2D6*

   D. *CYP3A5*

7. A patient with newly diagnosed atrial fibrillation will be starting warfarin. A SNP test is performed and reveals the *CYP2C9*2/*3* and *VKORC1* c.-1639 AA genotypes. Which of the following responses to warfarin would be predicted based on this genotype?

   A. Increased metabolism and usual sensitivity; use lower dose

   B. Decreased metabolism and decreased sensitivity; use higher dose

   C. Decreased metabolism and increased sensitivity; use lower dose

   D. Increased metabolism and decreased sensitivity; use higher dose

8. Screening for which of the following polymorphisms is indicated prior to carbamazepine use in a person of Southeast Asian descent?

   A. *CYP2D6*2*

B. *HLA-B*15:02*

C. *CYP2C9*2*

D. *TPMT*2*

9. Which gene predicts risk for muscle toxicity with simvastatin use?

A. *SLCO1B1*

B. *HLA-B*

C. *HMG-CoA*

D. *LDLR*

10. Which drug is recommended to reduce tumor progression in a patient with breast cancer who overexpresses the HER2 gene?

A. Mercaptopurine

B. Tamoxifen

C. Trastuzumab

D. Voriconazole

11. What is the CYP2D6 activity score and phenotype for a patient whose genotype is *CYP2D6*1/*4*?

A. 0 / poor metabolizer

B. 1 / intermediate metabolizer

C. 2 / normal metabolizer

D. 3 / ultrarapid metabolizer

12. What is the CYP2C19 phenotype for a patient whose genotype is *CYP2C19*17/*17*?

A. Ultrarapid metabolizer

B. Rapid metabolizer

C. Normal metabolizer

D. Poor metabolizer

13. If Drug X requires metabolism by a specific CYP enzyme into an active metabolite to produce its therapeutic effect, which phenotype of that enzyme is most likely to result in treatment failure?

A. Ultrarapid metabolizer

B. Normal metabolizer

C. Intermediate metabolizer

D. Poor metabolizer

14. Which of the following information is provided by the Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines?

A. When clinicians should order pharmacogenomic tests

B. How clinicians should use pharmacogenomic test results to guide prescribing

C. A searchable database of pharmacogenomics literature and guidelines

D. A table of pharmacogenomic biomarkers on FDA drug labels

15. Which of the following is true regarding the clinical implementation of pharmacogenomics?

A. Pharmacists can take a lead role in the clinical implementation of pharmacogenomics

B. Pharmacogenomics must be implemented as part of a research protocol

C. Opportunities for patients to obtain pharmacogenomic testing are decreasing

D. Pharmacogenomic information is more important that other clinical factors when making medication recommendations

SELF-ASSESSMENT QUESTION-ANSWERS

1. **B.** Genetic variation in drug-metabolizing enzymes and drug transporters may affect drug pharmacokinetics, whereas genetic variation in drug targets may affect drug pharmacodynamics.

2. **A.** A single nucleotide polymorphism (SNP) is the most commonly occurring variant in the human genome, occurring once approximately every 300 base pairs. SNPs occur when one nucleotide base pair replaces another, as illustrated in Fig. e7-2.

3. **D.** *CYP2D6* polymorphism can influence a patient’s risk of drug toxicity. For example, if a drug is primarily metabolized by CYP2D6 into inactive metabolites (eg, paroxetine), a CYP2D6 poor metabolizer can experience supratherapeutic plasma concentrations of drug at standard doses and may experience toxic effects as a result (see Fig. e7-3). In addition, CYP2D6 polymorphism can affect drug interaction potential. A patient who is a CYP2D6 poor metabolizer will not experience a drug-drug interaction with a strong CYP2D6 inhibitor, because there no enzyme activity to inhibit. In contrast, a CYP2D6 normal metabolizer who is exposed to a strong CYP2D6 inhibitor will act like a CYP2D6 poor metabolizer. This phenomenon is called phenoconversion.

4. **D.** Codeine is a prodrug that requires bioactivation via the CYP2D6 enzyme to morphine for analgesic effect. CYP2D6 poor metabolizers are unable to transform codeine into morphine and thus will not experience adequate analgesia with codeine. CYP2D6 intermediate metabolizers may also have reduced analgesia, but not to the extent of poor metabolizers.

5. **D.** *VKORC1* encodes for vitamin K epoxide reductase, which warfarin inhibits to exert its therapeutic effect. *TPMT* and *CYP2C19* are genes that encode for drug-metabolizing enzymes, and *SLCO1B1* is a gene that encodes for a drug transporter.

6. **B.** Clopidogrel is a prodrug that requires bioactivation via the CYP2C19 enzyme into active metabolites that exert its antiplatelet effects, as illustrated in Fig. e7-4.

7. **C.** Warfarin is metabolized into inactive metabolites via the CYP2C9 enzyme. Patients who carry the *CYP2C9*2* and/or *CYP2C9*3* alleles have decreased CYP2C9 enzyme activity and thus will have decreased warfarin metabolism. In addition, a common SNP in the *VKORC1* regulatory region, c.-1639G>A, significantly contributes to the interpatient variability in warfarin response, as it modulates *VKORC1* gene expression. Specifically, the –1639 AA, AG, and GG genotypes lead to high, intermediate, and low sensitivity to warfarin, respectively. The patient’s results, therefore, both indicate a need for a lower warfarin dose. Other clinical factors, such as age, body size, and vitamin K intake, may also influence warfarin dose.

8. **B.** The FDA label for carbamazepine has a boxed warning to screen patients of Southeast Asian descent for the presence of the *HLA-B*15:02* allele. Having this allele puts patients at risk for severe cutaneous adverse reactions, including Stevens–Johnson syndrome and toxic epidermal necrolysis.

9. **A.** The gene *SLCO1B1* predicts risk for muscle toxicity with simvastatin use. This gene encodes for an organic anion transporter that mediates the uptake of statins from the bloodstream into the liver. Patients who have reduced SLCO1B1 transporter function experience decreased simvastatin

clearance and may be at increased risk of myopathy.

10. **C.** The discovery of *HER2* overexpression and its effects on cancer prognosis led to the development of trastuzumab, a recombinant monoclonal antibody that targets HER2 and blocks HER2-stimulated growth and survival of cancer cells. The addition of trastuzumab to breast cancer chemotherapy significantly slows the progression of cancer and improves tumor response rates in women with HER2-positive tumors. Testing for HER2-overexpression is necessary to determine which patients may benefit from trastuzumab.

11. **B.** A genotype's activity score is the sum of the activity values for each allele. In this case, the activity score is the sum of 1 (activity value for **1*, a normal function allele) and 0 (activity value for **4*, a no-function allele), giving a total score of 1. A CYP2D6 activity score of 1 corresponds to an intermediate metabolizer. Refer to Table e7-4 for phenotype definitions based on genotype data for *CYP2D6*, *CYP2C19*, and *CYP2C9*.

12. **A.** Patients who inherit two copies of the *CYP2C19* increased function allele, **17*, are considered ultrarapid metabolizers. These individuals have increased *CYP2C19* gene expression, and thus, have increased CYP2C19 enzyme activity. Refer to Table e7-4 for phenotype definitions based on genotype data for *CYP2D6*, *CYP2C19*, and *CYP2C9*.

13. **D.** If the patient is a poor metabolizer of the enzyme, they will not be able to effectively metabolized the drug into its active form, which could result in subtherapeutic plasma concentrations of the active metabolite and treatment failure. Refer to Fig. e7-3, panel *B*, for a visual representation of this concept.

14. **B.** CPIC guidelines do not recommend whether genetic tests should be ordered, but rather, how to use existing genetic information to guide prescribing. The Pharmacogenomics Knowledgebase (PharmGKB) is a searchable database of pharmacogenomics literature and guidelines. The FDA maintains its own tables of pharmacogenomic biomarkers and pharmacogenetic associations on its Website.

15. **A.** As the medication experts, pharmacists are leading the clinical implementation of pharmacogenomics across healthcare settings as part of multidisciplinary teams. Pharmacogenomics is implemented both clinically and as part of research programs. Opportunities for patients to obtain pharmacogenomic testing are increasing, especially with increasing clinical and research programs as well as direct-to-consumer genetic testing. Genetic information needs to be considered in the context of other important clinical factors, such as age, body size, organ function, and concomitant drug therapy, when making medication recommendations.

Chapter e8: Clinical Toxicology

Bryan D. Hayes; Natalija M. Farrell

KEY CONCEPTS

KEY CONCEPTS

① Poisoning can result from exposure to excessive doses of any chemical, with medicines being responsible for most childhood and adult poisonings.

② The total number and rate of poisonings have been increasing, but preventive measures, such as child-resistant containers, have reduced mortality in young children.

③ Immediate first aid may reduce the development of serious poisoning, and consultation with a poison control center may indicate the need for further therapy.

④ The use of ipecac syrup, gastric lavage, whole bowel irrigation, and cathartics has fallen out of favor as routine therapies, whereas activated charcoal remains useful for gastric decontamination of appropriate patients.

⑤ Antidotes can prevent or reduce the toxicity of certain poisons, but symptomatic and supportive care is essential for all patients.

⑥ Acute acetaminophen poisoning produces severe liver injury and occasionally kidney failure. A determination of serum acetaminophen concentration may indicate whether there is risk of hepatotoxicity and the need for acetylcysteine therapy.

⑦ Anticholinesterase insecticides may produce life-threatening respiratory distress and paralysis by all routes of exposure and can be treated with symptomatic care, atropine, and pralidoxime.

⑧ An overdose of calcium channel antagonists can produce severe hypotension and bradycardia and should be treated with supportive care, calcium, and insulin with supplemental dextrose.

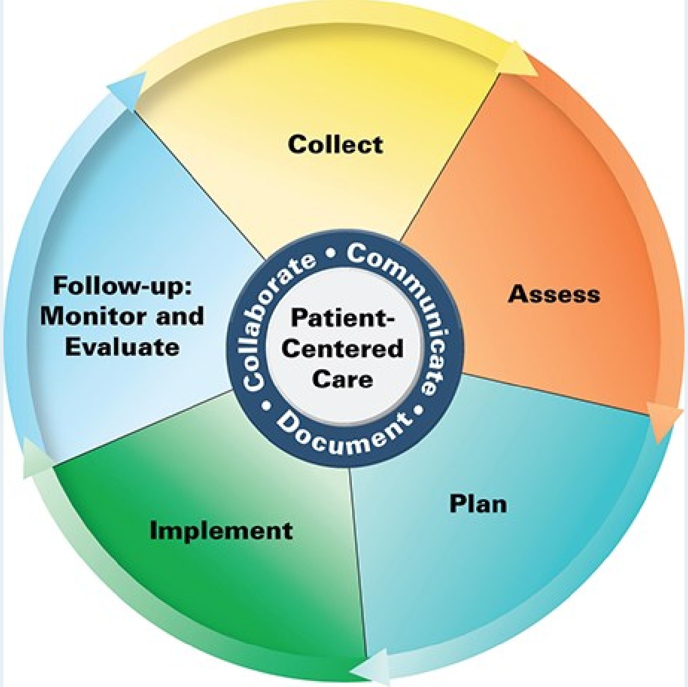
⑨ Anticholinergic toxicity is characterized by dry mucous membranes, mydriasis, urinary retention, tachycardia, fever, or agitated delirium with or without hallucinations, which can be treated with physostigmine.

⑩ Acute opioid poisoning and overdose can produce life-threatening respiratory depression that can be treated with assisted ventilation and naloxone.

⑪ Chemicals can be used for mass poisonings by acts of terrorism and warfare and typically produce life-threatening effects within minutes to hours, which warrant emergency preparedness at healthcare facilities and communities.

PATIENT CARE PROCESS

Patient Care Process for Prehospital Care of Acute Poisonings



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect (from patient, caregiver, or bystander)

- Patient symptoms (eg, none, minor, life threatening)
- Time of exposure
- Type of exposure (eg, ingestion, inhalation, injection, skin contact, eye contact)
- Substance(s) involved in the exposure
- Patient characteristics (eg, age, sex, weight)
- Circumstances of the exposure (eg, unintentional, substance abuse, self-harm)
- Patient health history (healthy, acute and chronic illnesses, pregnancy, recent hospitalization, substance use disorder)
- Prescription and nonprescription medications, dietary supplements, household products and chemicals in the vicinity
- Objective information
    - Estimate of the number of tablets or volume missing and possibly consumed
    - Exact name of the product and strength

Assess

- Presence of emergent symptoms (eg, unresponsiveness, seizures, shortness-of-breath, slowed or shallow breathing or if the exposure is likely to produce these symptoms within 1 hour)
- Presence of potential high-risk factors (eg, child-resistant container, signal words (Poison, Caution, Danger) on the product label; debilitated, elderly; suspected suicidal or homicidal intent; suspected child or elder abuse; substance abuse) (see Tables e8-1 and e8-4)
- Ability/willingness to contact a poison control center or call 9-1-1.

- Ability/willingness to ptrovide first aid (see Table e8-8) and naloxone if needed and available (see Table e8-13)

Plan[*]

- If emergent symptoms are present, call 9-1-1 for ambulance transport to the nearest hospital
- If unresponsive with depressed respirations and an opioid overdose is suspected, administer naloxone nasal spray or autoinjector by a trained bystander and/or call 9-1-1
- Referral to a poison control center (1-800-222-1222) to assess product toxicity, therapeutic actions, need for referral to a hospital
- If the patient does not need referral to a healthcare facility, explain self-monitoring instructions for development or resolution of symptoms

Implement[*]

- For hospitalized patients, assess whether the incident involves substance abuse, child or elder abuse, suicide or homicide attempt and engage appropriate healthcare professionals and law enforcement authorities
- For caregivers of children under the age of 6 years, provide poison prevention materials and instructions for contacting a poison control center
- If medications were mistakenly misused, referral to the patient's pharmacist for counseling

Follow-up: Monitor and Evaluate

- Patient's condition, response to treatment, resolution of any symptoms and adherence to referral—typical procedures when a poison control center is involved
- Adherence to "safety proofing" a household where preschool-aged children may be present

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Watch the video entitled "Toxicology—The National Emergency Medicine Board Review Course" <https://www.youtube.com/watch?v=LIfermvH8YU> up to minute 21:00. Dr. William 'Billy" Mallon, an emergency medicine physician, provides an overview of basic toxicology principles covered in this chapter including gastrointestinal decontamination, enhanced elimination, and antidotes. The video is useful to enhance student understanding of foundational concepts of clinical toxicology.

Poisoning is an adverse effect from a chemical that has been taken in excessive amounts. The body can tolerate and, in some cases, detoxify a certain dose of a chemical; however, toxicity ensues once a critical exposure threshold is exceeded. Poisoning can produce minor local effects that may be treated readily in the outpatient setting or systemic life-threatening effects that require intensive medical intervention. Virtually any chemical can become a poison when taken in enough quantity, but the potency of some compounds leads to serious toxicity with small quantities (Table e8-1). Poisoning by chemicals includes exposure to drugs, industrial chemicals, household products, plants, venomous animals, agrochemicals, and weapons for warfare and terrorism. This chapter describes some examples of the spectrum of toxicity, outlines means to recognize poisoning risk, and presents principles of treatment.

TABLE e8-1

Serious Toxicity in a Child Associated with Ingestion of One Mouthful or One Dosage Unit

Acids[a]	**Colchicine**
Anticholinesterase insecticides[a]	Cyanide[a]
Beta blockers	Diphenoxylate-atropine
Benzonatate	Hydrocarbons[a]
Calcium channel blockers	Methanol[a]
Caustics or alkalis[a]	Methyl salicylate[a]
Cationic detergents[a]	Opioids
Chloroquine	Phencyclidine or LSD
Chlorpromazine	Sulfonylureas
Clonidine	Theophylline
Cocaine	Tricyclic antidepressants

[a] Concentrated or undiluted form.

EPIDEMIOLOGY

Poisonings account for approximately 69,000 deaths, at least 2.3 million emergency department (ED) visits, and over 1.9 million nonfatal poisoning injuries each year in the United States.[1,2] Approximately 0.2% of poisoning deaths involve children younger than 5 years.[1] Of ED visits for drug-related poisoning, typically 1.1 million visits are made each year (3.5 per 100,000 population) with the highest rate observed for patients 20 to 34 years of age. One-fourth of ED visits for drug-related poisonings were hospitalized, which is twice the rate of other types of visits.[2] The age-adjusted death rates from poisonings from all circumstances have been increasing steadily, with a 297% increase from 2000 to 2016, representing 68,995 deaths representing 21.3 deaths per 100,000 population in 2016 of which 92% were drug-related poisonings. This increasing mortality trend has placed poisoning since 2008 as the leading cause of injury-related death in the United States.[1]

① Several databases in the United States provide different levels of insight into and documentation of the poisoning problem (Table e8-2). Poisonings documented by US poison centers are compiled in the annual report of the American Association of Poison Control Centers—National Poison Data System (AAPCC-NPDS).[3] Although it represents the largest database on poisoning, it is not complete because it relies on individuals voluntarily contacting a poison control center. The AAPCC-NPDS data set captures approximately 2% to 3% of the annual number of deaths from poisoning tabulated in death certificates.[1,3] Despite these shortcomings, AAPCC-NPDS provides valuable insight into the characteristics and frequency of poisonings in the community at large. In the 2019 AAPCC-NPDS summary, 2,148,141 poisoning exposures were reported by 55 poison centers that served the entire United States.[3] Children younger than 6 years accounted for 43% of cases. A residence was the site of exposure in 90% of the cases, and a single substance was involved in 88% of cases. An acute exposure (ie, all at one time) accounted for 85% of cases and 77% were unintentional or accidental exposures. Fatalities accounted for 1,411 (0.06%) cases, of which 52% resulted from suicide and 0.9% were children younger than 6 years of age. The distribution of substances most frequently involved in pediatric and adult exposures differed; however, medicines were the most frequently involved (49%) substances for all age groups (Table e8-3). Sixty-six percent of the poison exposures were treated at the scene. In summary, children account for most of the reported poison exposures, but a greater proportion of life-threatening poisonings are observed in adults.

TABLE e8-2

Comparison of Various Poisoning Databases

Database (Abbreviation)	Characteristics
Death certificates from state health departments compiled by the National Center for Health Statistics (NCHS) www.cdc.gov/injury/wisqars/	Compiles all death certificates whether the cause of death was by disease or external forces. Typically verified by laboratory and clinical observations.
National Electronic Injury Surveillance System—All Injury Program of US Consumer Product Safety Commission (NEISS) www.cpsc.gov/en/research--statistics/neiss-injury-data/	Surveys electronically all injuries, including poisonings, treated daily at approximately 100 emergency departments. Used to identify product-related injuries.
The American Association of Poison Control Centers—National Poison Data System (AAPCC-NPDS) www.aapcc.org	Represents largest database of poison exposures with high representation of children based on voluntary reporting to poison control centers.

TABLE e8-3

Poison Exposures by Age Group and Fatal Outcome, Ranked in Decreasing Order

Pediatric	Adult	Fatal Outcome
Cosmetics, personal care items	Medicines	Medicines
Cleaning substances	Cleaning substances	Alcohols
Medicines	Alcohols	Chemicals
Foreign bodies, toys	Pesticides	Gases, fumes
Dietary supplements	Cosmetics, personal care items	
Pesticides	Bites and envenomation	
Plants	Gases, fumes	

Data from Reference 3.

POISON PREVENTION STRATEGIES

② The number of poisoning deaths in children has declined dramatically over the past five decades, due, in part, to the implementation of several poison prevention approaches. These include the Poison Prevention Packaging Act (PPPA) of 1970, the evolution of regional poison control centers, the application of prompt first aid measures, improvements in overall critical care, development of less toxic product formulations, better clarity in the packaging and labeling of products, and public education on the risks and prevention of poisoning. Although all these factors play a role in minimizing poisoning dangers, particularly in children, the PPPA has perhaps had the most significant influence. The intent of the PPPA was to develop packaging that is difficult for children younger than 5 years of age to open or to obtain harmful amounts within a reasonable period. However, the packaging was not to be difficult for normal adults to use properly.[4] Safety packaging is required for several products and product categories (Table e8-4). Child-resistant containers are not totally childproof and may be opened by children, which can result in poisoning. Despite the success of child-resistant containers, many adults disable the hardware or simply use no safety cap, thus placing children at risk. Fatigue of the packaging materials can occur, which underscores the need for new prescription ware for refills, as required in the PPPA. During 2004 to 2010, ED visits for unsupervised exposures in pediatric patients increased by an average of 5.7% annually, with 75,842 in 2010. Over the next 4 years, there was an average decrease of 6.7% annually to 59,092 in 2013. Most exposures are due to opioids and benzodiazepines.[5] Additionally, improper storage of medications at home or when visiting other households, such as grandparent's homes, can contribute to accidental exposures in pediatric patients.[6,7] The "Up and Away" campaign promotes the storage of medications out of sight and out of reach of children,[8] which can help reduce unintentional pediatric medication overdoses.[7,8] Patients should be encouraged to properly dispose of medications that are outdated or no longer indicated to eliminate the risk of poisoning and drug diversion (see www.fda.gov/forconsumers/consumerupdates/ucm101653.htm).

TABLE e8-4

Examples of Products Requiring Child-Resistant Closures

Acetaminophen	Kerosene
Aspirin	Methanol
Diphenhydramine	Naproxen
Ethylene glycol	Oral prescription drugs[a]
Glue removers containing acetonitrile	Sodium hydroxide
Ibuprofen	Sulfuric acid
Iron pharmaceuticals	Turpentine

[a] With certain exceptions such as nitroglycerin and oral contraceptives.

Poison prevention requires constant vigilance. New generations of families must be educated on poisoning risks and prevention strategies. New products and changes in product formulations present different poisoning dangers and must be studied to provide optimal management. Changes in medication packaging such as unit-dose packaging or inclusion of flow restrictors for oral solutions has helped reduced pediatric overdoses involving iron and acetaminophen, respectively.[9,10] Strategies to prevent poisonings should consider the various psychosocial circumstances of poisoning (Table e8-5), prioritize risk groups and behaviors, and customize an intervention for specific situations.

TABLE e8-5

Psychosocial Characteristics of Poisoning Patients

Children	Adults	Elderly
Act purposefully or are poisoned by caretaker or sibling	Intentional abuse or suicidal intent is possible	Act with suicidal intent or unintentional misuse
Act with developmentally appropriate curiosity	Disregard or cannot read directions	Confuse product identity and directions for use
Attracted by product appearance	Do not recognize poisoning risk	Do not recognize poisoning risk
Ingest substances that adults find unpleasant	Reluctant to seek assistance until ill	Comorbid conditions complicate toxicity
React to stressful and disrupted household	Exaggerate or misrepresent situation	Unable or unwilling to describe situation
Imitate adult behaviors (eg, taking medicine)	Peer pressure to experiment with drugs	Multiple drugs may lead to adverse reactions

Recognition and Assessment

A clinician's initial responsibility is to determine whether a poisoning has occurred or a potential for development of a poisoning exists. Some patients provide a clear account of an exposure that occurred with a known quantity of a specific agent. Other patients appear with an unexplained illness characterized by nonspecific signs and symptoms and no immediate history of ingestion. Exposure to folk remedies, dietary supplements, and environmental toxins also should be considered. Patients with suicide gestures can deliberately give an unclear history, and poisoning should be suspected routinely. Poisoning and drug overdoses should be suspected in any patient with a sudden, unexplained illness or with a puzzling combination of signs and symptoms, particularly in high-risk age groups. Nearly any symptom can be seen with poisoning, but some signs and symptoms are suggestive of a particular toxin exposure. Compounds that produce characteristic clinical pictures (toxidromes), such as opioid poisoning with pinpoint pupils, central nervous system (CNS) depression, and respiratory depression, are most readily recognizable.[11] The recognition of chemicals responsible for acute mass emergencies resulting from industrial disasters, hazardous materials accidents, or acts of terrorism may be aided by evaluating characteristic signs and symptoms.[12] Some drugs may be adulterated or counterfeit products and delay appropriate recognition of a possible toxin.[13] Assessment of the patient may be aided by consultation with a poison control center. A center can provide information on product composition, typical symptoms, range of toxicity, laboratory analysis, treatment options, and bibliographic references. Furthermore, a center will have specially trained physicians, pharmacists, nurses, and toxicologists on staff or available for consultation to assist with difficult cases. Consultation with a poison control center also may identify changes in recommended therapy. A nationwide toll-free poison center access number (1-800-222-1222) routes callers to the poison control center serving the locality of the caller.

When the circumstances of a poison exposure indicate that it is minimally toxic, many poisonings can be managed successfully at the scene of the poisoning.[3,14] Poison control centers typically monitor the victim by telephone during the first 2 to 6 hours of the exposure to assess the patient's status and outcome of first aid.

Once a poisoning is suspected and confirmation of the diagnosis is needed for medical or legal purposes, appropriate biologic material should be sent to the laboratory for analysis. Gastric contents may contain the greatest concentration of drug, but they are difficult to analyze. Blood, saliva, or urine can be tested by qualitative screening to detect a drug's presence.[15,16] The results of a qualitative drug screen can be misleading because of interfering or low-level substances (Table e8-6); it rarely guides emergency therapy and thus has questionable value for nonspecific, general screening purposes.[15,16] Consultation with the laboratory technician and review of the assay package insert will help to determine the sensitivity and specificity of the assay. Quantitative determination of serum concentrations may be important for the assessment of some poisonings, such as acetaminophen, ethanol, iron, salicylates, and digoxin.[17]

TABLE e8-6

Considerations in Evaluating the Results of Some Common Immunoassays Used for Urine Drug Screening

Drug	Detection After Stopping Use	Comments
Amphetamines	2-5 days	Many sympathomimetic amines, such as pseudoephedrine, ephedra, phenylephrine, fenfluramine, and phentermine, may cause positive results
	Up to 2 weeks with prolonged or heavy use	Other drugs, such as selegiline, chlorpromazine, trazodone, ranitidine, and amantadine, may cause false-positive results depending on the assay
Benzodiazepines	• Up to 2 weeks • Up to 6 weeks with chronic use of some drugs	Ability to detect benzodiazepines varies by drug; oxaprozin, sertraline may cause false-positive results
Cannabinoid metabolite (marijuana)	• 7-10 days • Up to 1-2 months with prolonged or heavy use	Extent and duration of use will affect detection time. Drugs such as ibuprofen and naproxen may cause false-positive results depending on the assay
Cocaine metabolite (benzoylecgonine)	• 12-72 hours • Up to 1-3 weeks with prolonged or heavy use	Cocaine is metabolized rapidly, and specific metabolites are typically the substance detected. False-positive results from “caine” anesthetics and other drugs are unlikely
Opioids	• 2-3 days • Up to 6 days with sustained-release formulations • Up to 1 week with prolonged or heavy use	Because the assay was made to detect morphine, detection of other opioids, such as codeine, oxycodone, hydrocodone, and other semisynthetic opioids, may be limited. Some synthetic opioids, such as fentanyl and meperidine, may not be detected. Drugs such as rifampin and some fluoroquinolones may cause false-positive results depending on the assay
Phencyclidine	• 2-10 days	Drugs such as ketamine, dextromethorphan, diphenhydramine, venlafaxine, ibuprofen, meperidine, and

	• 1 month or more with prolonged or heavy use	tramadol may cause false-positive results depending on the assay

Pharmacogenetic Considerations

Pharmacogenetic factors responsible for poisoning risk among individuals have not been systematically studied, but unusual circumstances of poisoning cases have prompted the use of genotyping to identify polymorphically expressed drug metabolizing enzymes. The following three examples demonstrate this phenomenon. The antitussive drug, dextromethorphan is abused to achieve euphoric effects, which are not universally experienced at comparable doses. The dextromethorphan metabolite dextrorphan is responsible for the euphoria, dysphoria, hallucinations, and hyperactive behavior. Individuals who are cytochrome P450 (CYP) 2D6 extensive metabolizers are more apt to experience these euphoric effects.[18] Codeine has produced severe toxicity and death in some breast-fed infants, healthy young children, and older adults following the ingestion of typical doses. These individuals were ultrarapid CYP2D6 metabolizers of codeine, which resulted in the generation of life-threatening or fatal amounts of morphine, a metabolite of codeine.[19,20] Lastly, hydrocodone administration at higher than recommended doses resulted in death to a child who was a CYP2D6 poor metabolizer which reduced the capacity to metabolize hydrocodone to hydromorphone.[21]

Toxicokinetic Considerations

The pharmacokinetic characteristics of drugs taken in overdose may differ from those observed following therapeutic doses (Table e8-7).[22,23] These differences are the result of dose-dependent changes in absorption, distribution, metabolism, or elimination; pharmacologic effects of the drug; or pathophysiologic consequences of the overdose. Dose-dependent changes may decrease the rate and extent of absorption, whereas the bioavailability of the agent may be increased because of saturation of first-pass metabolism. Delayed gastric emptying by anticholinergic drugs or as the result of general CNS depression caused by many drugs may alter the rate and extent of absorption. Patients with a drug overdose may inherently exhibit prolonged gastric emptying and gastric hypomotility.[24] The formation of concretions or bezoars of solid dosage forms may delay the onset, prolong the duration, or complicate the therapy for an acute overdose.[25] A combination of pharmacokinetic and pharmacodynamic factors may lead to delayed onset of toxicity of several toxins, such as thyroid hormones, oral anticoagulants, acetaminophen, and drugs in sustained-release dosage forms. The distribution of a compound may be altered because of saturation of protein-binding sites. Drug-induced hypoperfusion may affect drug distribution and result in reduced hepatic or renal clearance. Changes in blood pH may alter the distribution of weak acids and bases. Metabolism and elimination of a compound may be retarded because of saturation of biotransformation pathways leading to nonlinear elimination kinetics. Drug-induced kidney or liver injury also can decrease clearance significantly. Implications of these changes for poisoning management include delayed achievement of peak concentrations with a corresponding longer period of opportunity to remove the drug from the gastrointestinal (GI) tract. The expected duration of effects may be much greater than that observed with therapeutic doses because of continued absorption and impaired clearance. The application of pharmacokinetic variables, such as percentage protein binding and volume of distribution, from therapeutic doses may not be appropriate in poisoning cases.[22,23] Data on toxicokinetics, the application of pharmacokinetic principles in the setting of overdose and toxicity, often are difficult to interpret and compare because the doses and times of ingestion are uncertain, the duration of sampling is inadequate, active metabolites may not be measured, protein binding typically is not assessed, and the severity of toxicity may vary dramatically.

TABLE e8-7

Examples of the Influence of Drug Overdosage on Pharmacokinetic and Pharmacodynamic Characteristics

Effect of Overdosage[a]	Examples
Slowed absorption due to formation of poorly soluble concretions in the gastrointestinal tract	Aspirin, lithium, phenytoin, sustained-release theophylline
Slowed absorption due to slowed gastrointestinal motility	Benztropine, nortriptyline
Slowed absorption due to toxin-induced hypoperfusion	Procainamide
Decreased serum protein binding	Lidocaine, salicylates, valproic acid
Increased volume of distribution associated with toxin-induced acidemia	Salicylates
Slowed elimination due to saturation of biotransformation pathways	Ethanol, phenytoin, salicylates, theophylline
Slowed elimination due to toxin-induced hypothermia (<35°C)	Ethanol, propranolol
Prolonged toxicity due to formation of longer-acting metabolites	Carbamazepine, dapsone, glutethimide, meperidine

[a] Compared to characteristics following therapeutic doses or resolution of toxicity.

GENERAL APPROACH TO TREATMENT

Prehospital Care

First Aid

③ The presence of adequate airway, breathing, and circulation should be assessed, and cardiopulmonary resuscitation should be initiated, if needed. The most important step in preventing a minor exposure from progressing to a serious intoxication is early decontamination of the poison. Basic poisoning first aid and decontamination measures (Table e8-8) should be instituted immediately at the scene of the poisoning. If there is any question about the potential severity of the poison exposure, a poison control center should be consulted as soon as possible (1-800-222-1222). Placing the patient on the left side while awaiting transport may afford easier clearance of the airway if emesis occurs and may slow the absorption of drug from the GI tract.[26]

TABLE e8-8

First Aid for Poison Exposures

Inhaled poison	Immediately get the person to fresh air. Avoid breathing fumes. Open doors and windows. If victim is not breathing, start artificial respiration.
Poison on the skin	Remove contaminated clothing and flood skin with water for 10 minutes. Wash gently with soap and water and rinse. Avoid further contamination of victim or first aid providers.
Poison in the eye	Flood the open eye with lukewarm or cool water poured from a glass 2 or 3 in. (~5-8 cm) before flushing the eye. Repeat for 10 to 15 continuous minutes. Remove contact lenses. Avoid ocular vasoconstrictor drops.
Swallowed poison	Provide supportive care.

Self-Care

④ Ipecac syrup had been used in the United States since the 1960s to induce vomiting for treatment of ingested poisons, but its use is no longer recommended due to negligible benefit. In 2003, the American Academy of Pediatrics issued a policy statement indicating that ipecac syrup was no longer to be used routinely to treat poisonings at home and that parents should discard any remaining product.[27] In 2010, ipecac syrup was no longer manufactured for use in the United States, but it still may be found in some households. Induced vomiting is not recommended via any mechanism, such as gagging, grease, salt, or hydrogen peroxide.

Hospital Treatment

Supportive and symptomatic care is the mainstay of treatment of a poisoned patient. In the search for specific antidotes and methods to increase excretion of the drug, attention to vital signs and organ functions should not be neglected. Establishment of adequate oxygenation and maintenance of adequate circulation are the highest priorities. Other components of the acute supportive care plan include the management of seizures, dysrhythmias, hypotension, acid-base balance, fluid status, electrolyte balance, and hypoglycemia. Placement of intravenous (IV) catheters is typical to ensure delivery of fluids and drugs when necessary.

Gastric Lavage

Gastric lavage involves the placement of an orogastric tube and washing out of the gastric contents through repetitive instillation and withdrawal of fluid. Gastric lavage is not recommended for routine use, if at all, and only by clinicians experienced in its use.[28] It may be considered for potentially life-threatening ingestions, when the ingestion occurred within 1 hour as a general guide, or when the substance is not absorbed by activated charcoal. If the patient is comatose or lacks a gag reflex, gastric lavage should be performed only after intubation with a cuffed or well-fitting endotracheal tube. Relative contraindications for gastric lavage include ingestion of a corrosive or hydrocarbon agent. Complications of gastric lavage include aspiration pneumonitis, laryngospasm, esophageal and gastric perforation and fluid and electrolyte imbalance.[28] Use of gastric lavage has declined in recent years as evidenced by the finding that only 0.1% of 658,242 cases treated at a healthcare facility received gastric lavage in the 2019 AAPCC-NPDS report.[3]

Single-Dose Activated Charcoal

Reduction of toxin absorption can be achieved by administration of activated charcoal. It is a highly purified, adsorbent form of carbon that prevents GI absorption of a drug by chemically binding (adsorbing) the drug to the charcoal surface. There are no toxin-related contraindications to its use, but it is generally ineffective for iron, lead, lithium, simple alcohols, and corrosives. It is not indicated for aliphatic hydrocarbons because of the increased risk for emesis and pulmonary aspiration. Activated charcoal is most effective when given within the first few hours after ingestion. Ideally it should be administered within the first hour, but still can be useful up to 2 to 4 hours is some situations, for example, delayed GI transit due to food, anticholinergics, opioids, and massive overdoses with high mortality profile.[29,30] The recommended dose of activated charcoal for a child (1-12 years old) is 25 to 50 g; for an adolescent or adult, the recommended dose is 25 to 100 g. Children younger than 1 year can receive 1 g/kg. Activated charcoal is mixed with water to make a slurry, shaken vigorously, and administered orally or via a nasogastric tube. Activated charcoal is contraindicated when the GI tract is not intact or when the airway is not protected.

Activated charcoal is relatively nontoxic, but two risks include (a) emesis following administration and (b) pulmonary aspiration of charcoal and gastric contents leading to pneumonitis in patients with an unprotected airway or absent gag reflex.[30] Some activated charcoal products contain sorbitol, a cathartic that may be associated with an increased incidence of emesis following use. Activated charcoal has been promoted for treatment of poisonings at home, but issues of safety, patient compliance, and effectiveness have not been proven in the home setting.[27,31] Single-dose activated charcoal use has remained relatively steady during the past decade, with 5.2% of 658,242 cases in patients treated in hospitals according to the 2019 AAPCC-NPDS report.[3]

Cathartics

Cathartics, such as magnesium citrate and sorbitol, were thought to decrease the rate of absorption by increasing GI elimination of the poison and the poison-activated charcoal complex, but their value is unproven. Poisoned patients do not routinely require a cathartic, and it is rarely, if ever, given without concurrent activated charcoal administration.[32] If used, a cathartic should be administered only once and only if bowel sounds are present. Infants, the elderly, and patients with impaired kidney function should be given saline cathartics cautiously, if at all.[32]

Whole-Bowel Irrigation

Polyethylene glycol electrolyte solutions, such as GoLYTELY and Colyte, are used routinely for whole-bowel irrigation prior to colonoscopy and bowel surgery. These solutions also can be used to decontaminate the GI tract of ingested toxins.[33] Large volumes of these osmotically balanced solutions are administered continuously through a nasogastric or duodenal tube for 4 to 12 hours or more. It quickly causes GI evacuation and is continued until the rectal discharge is relatively clear. This procedure may be indicated for certain patients in whom the ingestion occurred several hours prior to hospitalization and the drug still is suspected to be in the GI tract, such as drug smugglers who swallow condoms filled with cocaine.[34] In addition, patients who have ingested delayed-release or enteric-coated drug formulations or have ingested substances, such as iron, lithium, and potassium, that are not well adsorbed by activated charcoal may benefit from whole-bowel irrigation.[33] It should not be used in patients with a bowel perforation or obstruction, GI hemorrhage, ileus, or intractable emesis. Emesis, abdominal cramps, and intestinal bloating have been reported with whole-bowel irrigation.[33] During 2019, whole-bowel irrigation was used in 0.2% of 658,242 cases managed at a healthcare facility.[3]

Perspectives on Gastric Decontamination

Although there are a variety of options for gastric decontamination, the American Academy of Clinical Toxicology and the European Association of Poison Centers and Clinical Toxicologists have concluded that no means of gastric decontamination should be used routinely for a poisoned patient without careful consideration (position statements are available at http://www.clintox.org/resources/position-statements).[28,30,32,33] Therapy is generally most effective within the first hour, and effectiveness beyond this time cannot be supported or refuted with the available data. A clinical policy statement by the American College of Emergency Physicians concludes that activated charcoal is advocated for most patients when appropriate; however, no definitive recommendation can be made on the use of ipecac syrup, gastric lavage, cathartics, or whole-bowel irrigation.[35] The clinical policy also states that ipecac syrup is rarely of value in the ED and that the use of whole-bowel irrigation following ingestion of substances not well adsorbed by activated charcoal is not supported by evidence. In many cases treatment solely with activated charcoal or observation and supportive care should be considered. Ideally, activated charcoal should be administered within 1 to 2 hours of ingestion, but it still can be useful up to 2 to 4 hours or more in some situations (eg, delayed GI transit due to food, anticholinergics, opioids; or a massive overdose with a high likelihood of mortality).[29] Poison control centers may be a source of guidance on the contemporary application of gastric decontamination techniques for a specific patient.

Enhanced Elimination

Of the methods tried to increase the rate of excretion of poisons from the body, only diuresis, multiple-dose activated charcoal, and hemodialysis have demonstrated usefulness in select situations. These approaches should be considered only if the risks of the procedure are significantly outweighed by the expected benefits or if the recovery of the patient is seriously in doubt and the method has been shown to be helpful.

Diuresis

Diuresis can be used for poisons excreted predominantly by the renal route; however, most drugs and poisons are metabolized, and thus only a good urine flow (eg, 2-3 mL/kg/hr) needs to be maintained for most patients. Fluid and electrolyte balance should be monitored closely. Ionized diuresis by altering urinary pH may increase excretion of certain chemicals that are weak acids or bases by trapping ionized drug in the renal tubule and minimizing reabsorption.

Alkalinization of the urine to achieve a urine pH of 7.5 or greater for poisoning by weak acids such as salicylates or phenobarbital can be achieved by IV administration of sodium bicarbonate 1 to 2 mEq/kg (mmol/kg) bolus followed by an infusion of 100 to 150 mEq (mmol) in 1 L of dextrose 5% in water at 1.5 to 2 times the rate of maintenance fluid administration. Complications of urinary alkalinization include alkalemia, hypokalemia, alkalotic tetany, and inability to achieve target urinary pH values.[36] Acid diuresis may enhance the excretion of weak bases, such as amphetamines, but it should not be used because it risks worsening amphetamine-related rhabdomyolysis with corresponding acute kidney injury. Generally, diuresis or ionized diuresis is rarely indicated for poisoned patients because it is inefficient relative to other methods of enhancing elimination, it is associated with a risk of unacceptable adverse effects, and renal elimination of most drugs is not enhanced dramatically.

Multiple-Dose Activated Charcoal

Multiple doses of activated charcoal can augment the body's clearance of certain drugs by enhanced passage from the bloodstream into the GI tract and subsequent adsorption. This process, termed *charcoal intestinal dialysis* or *charcoal-enhanced intestinal exsorption*, describes the attraction of drug molecules across the capillary bed of the intestine by activated charcoal in the intestinal lumen and subsequent adsorption of the drug to the charcoal. Furthermore, it may interrupt the enterohepatic recirculation of certain drugs. Once the drug is adsorbed to the charcoal, it is eliminated with the charcoal in the stool. Systemic clearance of several drugs has been shown to be enhanced up to severalfold.[37] An international toxicology group's position statement on multiple-dose activated charcoal concluded that it should be considered only if a patient has ingested a life-threatening amount of carbamazepine, dapsone, phenobarbital, quinine, or theophylline.[37] Although a prospective, randomized study of the effects of multiple-dose activated charcoal on phenobarbital-overdosed patients demonstrated increased drug elimination, no demonstrable effect on patient outcome was observed.[38]

This approach provides a rapid onset of action that is limited by blood flow and a maximal "ceiling effect" related to the dose of charcoal present in the intestine. The response to multiple-dose activated charcoal is greatest for drugs with the following characteristics: good affinity for adsorption by activated charcoal, low intrinsic clearance, sufficient residence time in the body (long serum half-life), long distributive phase, and low or nonrestrictive protein binding. A small volume of distribution is desirable, but it has a marginal influence as an isolated characteristic,[39] particularly if multiple-dose activated charcoal is instituted during the toxin's distributive phase. A typical dosage schedule is 12.5 to 25 g of activated charcoal every 2 to 6 hours until serious symptoms abate, or the serum concentration of the toxin is below the toxic range. This procedure has been used in premature and full-term infants in doses of 1 g/kg every 1 to 4 hours. Activated charcoal formulations without sorbitol should be used for multiple-dose activated charcoal regimens, because repeated doses of activated charcoal formulations with sorbitol increase the risk of adverse effects including dehydration, hypotension, and electrolyte derangements.[32,37] Serious complications, such as pulmonary aspiration, occur in less than 1% of patients.[40] The risks of aspiration pneumonitis in obtunded or uncooperative patients and of intestinal obstruction in patients prone to ileus following a period of bowel ischemia (eg, after cardiopulmonary arrest in the elderly) may be higher.[40] Contraindications are the same as those for single-dose charcoal.[30,37]

Hemodialysis

Intermittent hemodialysis or other extracorporeal dialytic therapies including continuous renal replacement therapies (eg, continuous veno-venous hemofiltration [CVVH]) may be necessary for certain severe cases of poisoning. Dialysis should be considered when the duration of symptoms is expected to be prolonged, normal pathways of excretion are compromised, clinical deterioration is present, the drug is dialyzable (ie, cleared by dialysis hemofilters), and appropriate personnel and equipment are available. Drugs that are dialyzable typically exhibit similar physiochemical and pharmacokinetic properties that collectively render them amenable to extracorporeal clearance. For example, drugs exhibiting a low molecular mass (<1,000 daltons), low protein binding (<80%), and a small to modest volume of distribution (<1 L/kg) are generally dialyzable.[41,42] The principles of renal replacement therapy for acutely ill individuals and patients with chronic kidney disease are described in Chapters 61 and 64, respectively. Although hemodialysis can provide an efficient means of enhanced elimination, it can pose serious risks related to anticoagulation, blood transfusions, loss of blood elements, fluid and electrolyte disturbances, and infection. Hemodialysis may be lifesaving for methanol and many ethylene glycol poisonings and effective for other poisons, such as lithium, salicylates, and theophylline. Another dialysis technique is CVVH that transports drugs across a semipermeable membrane primarily by convection in response to hydrostatic pressure gradients (described in Chapter 61).[41,42] Limited experience is reported with the use of hemofiltration for poisonings, but it may be attractive for the hemodynamically unstable patient who cannot tolerate hemodialysis. The Extracorporeal Treatments in Poisoning Workgroup (EXTRIP) has published several evidence-based guidelines on the use of extracorporeal methods on specific poisons (http://www.extrip-workgroup.org/).

Antidotes

⑤ The search for and use of an antidote should not replace good supportive care. Specific systemic antidotes are available for many common poisonings (Table e8-9).[43] Inadequate stocking, maintenance of supplies, and corresponding shortages of antidotes at acute care hospitals have been noted throughout the United States and can complicate the care of a poisoned patient.[43,44] An evidence-based consensus of experts has recommended minimum stocking requirements for 24 antidotes for acute care hospitals and that 12 should be available for immediate administration on patient arrival.[45] These recommendations may provide guidance to pharmacy and therapeutics committees in establishing a hospital's antidote needs. Drugs used conventionally for non-poisoning situations may act as antidotes to reverse acute toxicity, such as insulin-dextrose for β-adrenergic blocker or calcium channel antagonist overdose, glucagon for β-adrenergic blocker overdose, and octreotide for sulfonylurea-induced hypoglycemia.[43,46] Commercially available IV lipid emulsion has been used to reduce cardiac and CNS toxicity from several lipid-soluble drugs, such as local anesthetics, and is sometimes used as a "rescue" for patients with non-local anesthetic poisoning.[47] IV lipid emulsion is thought to work through several mechanisms, including redistribution away from critical organs (lipid shuttle) and non-scavenging effects such as acting as an energy substrate for affected organs.[48] There are several dosing schemes that involve single or multiple boluses followed by a continuous infusion, but none are well studied. The literature seems to support the use of IV lipid emulsion therapy for local anesthetic toxicity. Some human case studies report IV lipid emulsion therapy producing dramatic improvements in clinical status for non-local anesthetic overdose (eg, amlodipine). Others report no effect, or even worsening clinical status. Evidenced-based recommendations were only possible for a few types of poisoning based on low quality evidence available at the time of publication. Dose-finding and controlled studies in human poisoning are needed to further elucidate its role. Lastly, the use of toxin-specific antibodies (eg, fragment antigen binding [Fab] antibody fragments for digoxin or North American crotaline snake venom) has offered a new approach to treatment of poisoning victims.[43]

TABLE e8-9

Systemic Antidotes Available in the United States

Toxic Agent	Antidote
Acetaminophen	Acetylcysteine
Anticholinesterase insecticides	Atropine
Anticholinergics	Physostigmine
Benzodiazepines	Flumazenil

Botulism	Botulism antitoxin
Carbon monoxide	Oxygen
Cyanide	Sodium nitrate and sodium thiosulfate
Cyanide	Hydroxocobalamin
Dabigatran	Idarucizumab
Digoxin	Digoxin immune Fab
Ethylene glycol, methanol	Ethanol
Ethylene glycol, methanol	Fomepizole
Factor Xa inhibitor (apixaban, rivaroxaban)	Coagulation factor Xa [recombinant], inactivated-zhzo
Heavy metals (copper, lead)	Dimercaprol
Heavy metals (copper, lead)	Penicillamine
Iron	Deferoxamine
Isoniazid	Pyridoxine
Lead	Edetate calcium disodium
Lead	Succimer
Methemoglobinemia	Methylene blue
Opioids	Naloxone
Organophosphate insecticides	Pralidoxime
Radioactive americium, curium, plutonium	Diethylenetriaminepentaacetate
Radioactive iodine	Potassium iodide
Scorpion	*Centruroides* immune Fab
Snake, coral	*Micrurus fulvius* antivenin
Snakes (rattlesnakes, cottonmouth, copperhead)	*Crotalidae* polyvalent immune Fab
Snakes (rattlesnakes, cottonmouth, copperhead)	*Crotalidae immune F(ab') 2 (equine)*
Spider, black widow	*Lactrodectus mactans* antivenin
Thallium or cesium	Prussian blue

Tubocurarine	Neostigmine
Warfarin	Phytonadione and Prothrombin Complex Concentrate

Fab, fragment antigen binding.

Assessing the Effectiveness of Therapies

Case reports, clinical studies, human volunteer studies, animal investigations, and in vitro tests yield findings with limited generalizability to the care of humans who have been poisoned. Case reports are difficult to assess because they are uncontrolled, the histories are uncertain, and multiple therapies frequently are used. Although clinical studies may describe tens to hundreds of patients, they can exhibit serious shortcomings, such as weak randomization procedures, no laboratory confirmation or correlation with history, insufficient number of severe cases, no control group, and no quantitative measure of outcome. Extrapolation of data from human volunteer studies to patients who overdose is difficult because of potential or unknown variations in pharmacokinetics (eg, differing dissolution, gastric emptying, and absorption rates) seen with toxic as opposed to therapeutic doses,[22,23] differences in time to institute therapy in the emergency setting, and differences in absorption in fasted human volunteers compared with the full stomach of some patients who overdose. However, these studies provide the most controlled and objective measures of the efficacy of a treatment. Experiences from animal studies cannot be applied directly to humans because of interspecies differences in toxicity and metabolism. In vitro tests serve to screen the efficacy of some approaches, such as activated charcoal adsorption, but they do not mimic physiologic conditions sufficiently to allow direct clinical application of the findings. Despite their limitations, these data compose the evidence base for the therapy of poisoned patients and are tempered with the consideration of nonpoisoning-related factors such as a patient's underlying medical condition, age, and need for concurrent supportive measures.

CLINICAL SPECTRUM OF POISONING

Poisoning and drug overdose with acetaminophen, anticholinesterase insecticides, calcium channel blockers, anticholinergics, opioids, and weapons of mass chemical poisoning are the focus of the remainder of this chapter. These agents were chosen because they provide examples of different mechanisms of toxicity and the application of general treatment approaches, as well as some agent-specific pharmacotherapeutic interventions.

Acetaminophen

Clinical Presentation

⑥ Acute acetaminophen poisoning characteristically results in hepatotoxicity and is a leading cause of acute liver failure in the United States.[49] Clinical presentation is dependent on the time since ingestion, presence of risk factors, and the ingestion of other drugs. During the first 12 to 24 hours after ingestion, nausea, vomiting, anorexia, and diaphoresis may be observed; however, many patients are asymptomatic. During the next 1 to 3 days, which is a latent phase of lessened symptoms, patients often have an asymptomatic rise in liver enzymes and bilirubin. Signs and symptoms of hepatic injury become manifest 3 to 5 days after ingestion and include right upper quadrant abdominal tenderness, jaundice, hypoglycemia, and encephalopathy. Prolongation of the international normalized ratio (INR) worsens as hepatic necrosis progresses and may lead to disseminated intravascular coagulopathy. Patients with severe hepatic damage may develop hepatic encephalopathy (coma) and hepatorenal syndrome, and death can occur.[49,50] Survivors of severe hepatotoxicity usually exhibit no residual functional or histologic abnormalities of the liver within 1 to 6 months of the incident.[51]

Mechanism of Toxicity

Acetaminophen is metabolized in the liver primarily to glucuronide or sulfate conjugates, which are excreted into the urine with small amounts (<5%) of unchanged drug. Approximately 5% of a therapeutic dose is metabolized by CYPs, primarily CYP2E1, to the reactive metabolite *N*-acetyl-*p*-benzoquinoneimine (NAPQI). Normally, NAPQI is subsequently conjugated with glutathione, a sulfhydryl-containing compound, in the hepatocyte and excreted in the urine as a non-toxic mercapturate conjugate (Fig. e8-1).[49]

CLINICAL PRESENTATION: Acute Acetaminophen Poisoning

General

- No or mild nonspecific symptoms within 6 hours of ingestion.

Symptoms

- Nausea, vomiting, and abdominal discomfort within 1 to 12 hours after ingestion.
- Right upper abdominal quadrant tenderness, typically within 1 to 2 days.

Signs

- Typically, no signs present within first day.
- Jaundice, scleral icterus, and bleeding within 3 to 10 days.
- Oliguria occasionally within 2 to 7 days.
- With severe poisoning, hepatic encephalopathy (delirium, depressed reflexes, and coma) within 5 to 10 days.

Laboratory Tests

- Toxic serum acetaminophen concentration no earlier than 4 hours after ingestion by comparison with nomogram.
- Elevated aspartate aminotransferase (AST), alanine aminotransferase (ALT), serum bilirubin, and INR; hypoglycemia within 1 to 3 days.
- Elevated serum creatinine and blood urea nitrogen (BUN) within 2 to 7 days.

Sulfate stores are depleted in an acute overdose situation. This leads to increased acetaminophen metabolism via CYP2E1 and eventual depletion of the available glutathione used to detoxify NAPQI, which then reacts with other hepatocellular sulfhydryl compounds. This results in centrilobular hepatic necrosis.[49] Several other mechanisms, such as cytokine release and oxidative stress, also may be initiated by the initial cellular injury.[49]

In many cases of severe hepatotoxicity, impaired kidney function also is present and may range from oliguria to acute kidney injury. The etiology of the impaired kidney function may be a direct effect of NAPQI, generated by renal cytochrome oxidase, or a consequence of hepatic injury resulting in hepatorenal syndrome.[50]

Causative Agents

Acetaminophen, also known as paracetamol, is available widely without prescription as an analgesic and antipyretic. It is available in various dosage forms, including oral extended-release preparations, rectal suppositories, and an IV formulation. Acetaminophen may be combined with other drugs, such as antihistamines or opioid analgesics, and marketed in cough and cold preparations, menstrual remedies, and allergy products. Some patients may not recognize that they are consuming several products containing acetaminophen, which can increase the total dose, systemic exposure, and the subsequent risk of hepatotoxicity.

Incidence

Acetaminophen is commonly ingested by small children and is used frequently in suicide attempts by adolescents and adults.[3] Each year acetaminophen accounts for approximately 78,000 ED visits with 78% related to acts of self-harm.[52] The 2019 AAPCC-NPDS report documented 53,295 nonfatal single-drug product exposures and 127 deaths from acetaminophen alone, with 39% of the exposures in children younger than 6 years. Another 16,285 exposures were from combination drug products containing acetaminophen.[3]

Age-based differences in the metabolism of acetaminophen is responsible for major differences in the incidence of serious toxicity. Despite the common ingestion of acetaminophen by young children, few develop hepatotoxicity from acute overdosage.[3] In children younger than 9 to 12 years, acetaminophen undergoes more sulfation and less glucuronidation. The reduced fraction available for metabolism by CYPs may explain the rare development of serious toxicity in young children who take large overdoses. Earlier treatment intervention and spontaneous emesis also may reduce the risk of toxicity in children.

Risk Assessment

Acute, single-ingestion of at least 10 g or 200 mg/kg, whichever is less, of acetaminophen by patients 6 years or older is associated with development of hepatotoxicity (200 mg/kg or more of acetaminophen in children younger than 6 years).[53] Patients have survived much larger doses, particularly with early treatment. Initial symptoms, if present, do not predict the severity of the toxicity that eventually occurs.

Repeated ingestion of supratherapeutic doses of acetaminophen has been associated with hepatotoxicity in adults and children.[53–56] Patients who are fasting or have ingested alcohol in the preceding 5 days are at greater risk.[57] Young children have a higher risk when they have been acutely fasting as the result of a febrile illness or gastroenteritis.[56] Patients should be referred for medical evaluation if there is evidence that the ingestion exceeded 4 g/day or 100 mg/kg/day, whichever is less for 2 or more days.[53]

Chronic exposure to drugs that induce CYPs—specifically CYP2E1, which is responsible for most of the formation of NAPQI—may increase the risk of acetaminophen hepatotoxicity. Poorer outcomes have been noted in patients who chronically ingest alcohol and those receiving anticonvulsants, both known to induce CYP2E1.[51] Patients with chronic alcoholism have 3.5 greater odds of mortality with acute acetaminophen poisoning.[55]

The risk of developing hepatotoxicity with acute ingestion of acetaminophen may be predicted with a commonly used nomogram that is based on the acetaminophen serum concentration and time after ingestion.[57] The nomogram used in the United States is readily available in the United States Food and Drug Administration (FDA) approved package insert for acetylcysteine (available at: http://dailymed.nlm.nih.gov/) and in several electronic information databases (eg, Micromedex, UpToDate). Treatment should be started if the patient's serum concentration is above the line on the nomogram that starts at 150 mcg/mL (1,000 µmol/L) at 4 hours. If the plasma concentration plotted on the nomogram falls above the nomogram treatment line, indicating that hepatic damage is possible, a course of treatment with acetylcysteine is indicated. When the results of the acetaminophen determination will be available later than 8 hours after the ingestion, acetylcysteine therapy should be initiated based on the history and later discontinued if the results indicate nontoxic concentrations.[57] Outside of the United States, other countries have adopted a lower threshold on the nomogram for the treatment of acetaminophen toxicity.[58,59]

The nomogram is not useful for assessing chronic or supratherapeutic exposures to acetaminophen. Some have advocated that patients with chronic alcoholism should be treated with acetylcysteine regardless of the risk estimation.[55,60] Assessment and management of IV administered acetaminophen is presently similar to the acute oral overdose.[61]

Management of Toxicity

Therapy of an acute acetaminophen overdose depends on the amount ingested, time after ingestion, and serum concentration of acetaminophen. When excessive amounts are ingested, the history is unclear, or an intentional ingestion is suspected, the patient should be evaluated at an ED and acetaminophen serum concentrations obtained. Prehospital care generally is not indicated.[53] If the patient presents to the ED within 4 hours of the ingestion or ingestion of other drugs is suspected, one dose of activated charcoal can be administered.

Acetylcysteine (also known as *N*-acetylcysteine), a sulfhydryl-containing compound, replenishes the hepatic stores of glutathione by serving as a glutathione surrogate that combines directly with reactive metabolites or by serving as a source of sulfate, thus preventing hepatic damage.[62] It should be started within 10 hours of the ingestion to be most effective.[57] Initiation of therapy 24 to 36 hours after the ingestion may be of value in some patients, particularly those with measurable serum acetaminophen concentrations.[62,63] Patients with fulminant hepatic failure may benefit through other mechanisms by the administration or initiation of acetylcysteine several days after ingestion.[62,63]

Oral and IV formulations of acetylcysteine are available for clinical use. While there is no clear evidence favoring one formulation over the other,[64] there are several notable differences between them (Table e8-10).[62,64,65] Most notable is the occurrence (approximately 10% of cases) of anaphylactoid reactions (see Chapter e108) following the IV infusion. Acetylcysteine IV was used 10 times more frequently than the oral form as reported in the 2019 AAPCC-NPDS.[3] When acetaminophen plasma concentrations are below the nomogram treatment line, there is little risk of toxicity, protective therapy with acetylcysteine is not necessary, and medical therapy likely is unnecessary.[57,62] The acetaminophen blood sample should be drawn no sooner than 4 hours after the ingestion to ensure that peak acetaminophen concentrations have been reached. If a concentration is obtained less than 4 hours after ingestion, it is not interpretable, and a second determination should be done at least 4 hours after ingestion. Serial determinations of a serum concentration, 4 to 6 hours apart, typically are unnecessary unless there is some evidence of slowed GI motility as the result of the ingestion of certain drugs (eg, opioids, or anticholinergics), when an extended-release product is involved or if chronic or supratherapeutic overdoses are suspected. In these circumstances, therapy with acetylcysteine is continued if any concentration is above the treatment line of the nomogram, and provisional therapy is discontinued when both concentrations are below the treatment line. Several alternative dosing regimens for acetylcysteine with different duration, administration technique, and clinical endpoints have been proposed.[65,66] The 72-hour oral acetylcysteine and the 21-hour ("three—bag") IV regimen are satisfactory for most patients, but some state that the 72-hour regimen is too long while others believe the 21-hour regimen is too short. Individualized therapy based on clinical end points, for example, absence of acetaminophen in the blood at the end of a regimen, presence of hepatic encephalopathy or ALT approaching normal range, has been proposed as an alternative to strict adherence to the duration in the package insert. Several alternative, higher acetylcysteine dosing regimens have been described in the literature for massive acetaminophen overdoses,[67] but the number of patients in the studies has been relatively small and the findings are not generalizable. Similarly, "two-bag" acetylcysteine IV regimens have been described in literature and suggest reduced adverse effects and delays in treatment compared to the traditional, "three-bag" method.[68–72] For both the higher dose regimen and "two-bag" method, accepted and validated criteria are lacking at present.

TABLE e8-10

Comparison of the FDA Approved IV and Oral Regimens for Acetylcysteine in the Treatment of Acute Acetaminophen Poisoning

Characteristic	IV	Oral
Regimen	150 mg/kg in 200 mL D_5W infused over 1 hour, then 50 mg/kg in 500 mL D_5W over 4 hours, followed by 100 mg/kg in 1,000 mL D_5W over 16 hours[a]	140 mg/kg, followed 4 hours later by 70 mg/kg every 4 hours for 17 doses diluted to 5% with juice or soft drinks
Total dose (mg/kg)	300	1,330
Duration (hr)	21	72
Adverse effects	Nausea, vomiting; anaphylactoid reactions (rash, hypotension, wheezing, dyspnea); acute flushing and erythema in first hour of the infusion that typically resolves spontaneously	Nausea, vomiting
Ancillary therapy, if needed	Antihistamines and epinephrine for severe anaphylactic reactions	Antiemetics
Trade name	Acetadote	Mucomyst
Available strength	20%	10%, 20%

FDA, Food and Drug Administration; D_5W, 5% dextrose in water for injection.

[a] For patients <40 kg and those requiring fluid restriction, the total volume for dilution should be reduced as directed in the package insert.

Although young children have an inherently lower risk of acetaminophen-induced hepatotoxicity, these patients are managed in the same manner as adults. When acetaminophen serum concentrations predict that toxicity is probable, young children should receive acetylcysteine in the dosing regimen described previously.[66]

Hemodialysis may be considered in rare cases when serum acetaminophen concentrations are exceedingly high (>700-1,000 mcg/mL [>4,600-6,600 μmol/L]) with the early development of altered mental status and severe metabolic acidosis prior to the onset of hepatic failure.[73] If fulminant hepatic failure develops, the approaches described in Chapter e56 should be considered. In patients unresponsive to acetylcysteine, liver transplantation is a lifesaving option.[51]

Monitoring and Prevention

Baseline liver function tests (AST, ALT, bilirubin, INR), and serum creatinine concentration should be obtained on admission and repeated at 24-hour intervals until at least 96 hours have elapsed for patients at risk. Most patients with liver injury develop elevated transaminase concentrations within 24 hours of ingestion. Serum concentrations of AST or ALT greater than 1,000 international units per liter (IU/L) (16.7 μkat/L) commonly are associated with other signs of liver dysfunction and have been used as the threshold concentration in outcome studies to define severe liver toxicity.[57] The extent of transaminase elevation is not correlated directly with the severity of hepatic injury, with nonfatal cases demonstrating peak concentrations as high as 30,000 IU/L (500 μkat/L) between 48 and 72 hours after ingestion.[51] The King's College Criteria for acetaminophen toxicity (arterial pH <7.30, INR >6.5 or PT >100 s, creatinine ≥3.4 mg/dL (300 μmol/L), or Grade III-IV hepatic encephalopathy) is used to determine patients with acetaminophen toxicity that may benefit from a liver transplant and thus require transportation to a liver transplant center.[74,75]

Prevention of acetaminophen poisoning is based on recognition of the maximum daily therapeutic doses (4 g in adults), observance of general poison prevention practices, and early intervention in cases of suspected overdose. The frequent involvement of acetaminophen in poisonings and overdoses, whether declared by the patient, has led to the routine determination of acetaminophen concentrations in patients admitted to EDs for any overdose.[60]

Anticholinesterase Insecticides

Clinical Presentation

⑦ The clinical manifestations of anticholinesterase insecticide poisoning include any or all of the following: pinpoint pupils, excessive lacrimation, excessive salivation, bronchorrhea, bronchospasm, and expiratory wheezes, hyperperistalsis producing abdominal cramps and diarrhea, bradycardia, excessive sweating, fasciculations and weakness of skeletal muscles, paralysis of skeletal muscles (particularly those involved with respiration), convulsions, and coma.[76] Helpful mnemonics include DUMBELLS (diarrhea, urination, miosis, bradycardia/bronchospasm/bronchorrhea, emesis, lacrimation, lethargy, salivation) and SLUDGE + the Killer Bs (salivation, lacrimation, urination, defecation, GI symptoms, emesis + bradycardia/bronchospasm/bronchorrhea). Importantly, the life-threatening problems are bronchorrhea, bronchospasm, and bradycardia, hence the “Killer Bs” terminology. Symptoms of anticholinesterase poisoning and their response to antidotal therapy depend on the action of excessive acetylcholinesterase at different receptor types (Table e8-11).

TABLE e8-11

Effects of Acetylcholinesterase Inhibition at Muscarinic, Nicotinic, and CNS Receptors

Muscarinic Receptors	**Nicotinic-Sympathetic Neurons**
Diarrhea	Increased blood pressure
Urination	Sweating and piloerection
Miosis[a]	Mydriasis[a]
Bronchorrhea	Hyperglycemia
Bradycardia[a]	Tachycardia[a]
Emesis	Priapism
Lacrimation	**Nicotinic-neuromuscular neurons**
Salivation	Muscular weakness
CNS receptors (mixed type)	Cramps
Coma	Fasciculations
Seizures	Muscular paralysis

[a] Generally muscarinic effects predominate, but nicotinic effects can be observed.

CLINICAL PRESENTATION: Anticholinesterase Insecticide Poisoning

General

- Mild symptoms may resolve spontaneously; life-threatening toxicity may develop with 1 to 6 hours of exposure.

Symptoms

- Diarrhea, diaphoresis, excessive urination, miosis, blurred vision, pulmonary congestion, dyspnea, vomiting, lacrimation, salivation, and shortness of breath within 1 hour.
- Headache, confusion, coma, and seizures possible within 1 to 6 hours.

Signs

- Increased bronchial secretions, tachypnea, rales, and cyanosis within 1 to 6 hours.
- Muscle weakness, fasciculations, and respiratory paralysis within 1 to 6 hours.
- Bradycardia, atrial fibrillation, atrioventricular block, and hypotension within 1 to 6 hours.

Laboratory Tests

- Markedly depressed serum pseudocholinesterase activity.
- Altered arterial blood gases (acidosis), serum electrolytes, BUN, and serum creatinine in response to respiratory distress and shock within 1 to 6 hours.

Other Diagnostic Tests

- Chest radiographs for progression of pulmonary edema or hydrocarbon pneumonitis in symptomatic patients.
- Electrocardiogram (ECG) with continuous monitoring and pulse oximetry for complications from toxicity and hypoxia.

The time of onset and severity of symptoms depend on the route of exposure, potency of the agent, and total dose received. Toxic signs and symptoms develop most rapidly after inhalation or IV injection and slowest after skin contact. Anticholinesterase insecticides are absorbed through the skin, lungs, conjunctivae, and GI tract. Severe symptoms can occur from absorption by any route. Most patients are symptomatic within 6 hours, and death may occur within 24 hours without treatment. Death typically is caused by respiratory failure resulting from the combination of pulmonary and cardiovascular effects (Fig. e8-2).[76] Poisoning may be complicated by aspiration pneumonia, urinary tract infections, and sepsis.[76,77]

FIGURE e8-2

Pathogenesis of life-threatening effects of organophosphate poisoning.

Organophosphate poisoning has been associated with several residual effects, such as intermediate syndrome, extrapyramidal symptoms, neuropsychiatric effects, and delayed chronic neuropathy. Intermediate syndrome becomes manifest in some patients approximately 1 to 3 days after exposure and generally resolves within weeks of onset without further treatment. It is characterized by muscle weakness of proximal limbs, cranial nerve innervated muscles, and muscles of respiration. The inability of the patient to raise his or her head is often an initial sign. Extrapyramidal symptoms, which may develop 1 to 7 days after exposure, usually resolve spontaneously within a few days of onset. Neuropsychiatric effects, such as confusion, lethargy, memory impairment, headache, and depression, typically begin weeks to months after exposure and may last for years. Chronic neuropathy often presents as cramping muscle pain in the legs (upper extremities are sometimes involved), followed by rapidly progressive weakness and paralysis and develops 1 to 5 weeks after recovery from the acute poisoning exposure. Paresthesia and pain may persist and are unresponsive to further atropine or pralidoxime therapy. Improvement may be delayed for months to years, and in some cases the patient develops permanent disability. Chronic neuropathy is not associated with all organophosphates.[76]

Mechanism of Toxicity

Anticholinesterase insecticides phosphorylate the active site of cholinesterase in all parts of the body.[76] Inhibition of this enzyme leads to accumulation of acetylcholine at affected receptors and results in widespread toxicity. Acetylcholine is the neurotransmitter responsible for physiologic transmission of nerve impulses from preganglionic and postganglionic neurons of the cholinergic (parasympathetic) nervous system, preganglionic adrenergic (sympathetic) neurons, neuromuscular junction in skeletal muscles, and multiple nerve endings in the CNS (Fig. e8-3).

FIGURE e8-3

Organization of neurotransmitters of the peripheral nervous system and site of acetylcholinesterase action. (ACh, acetylcholine; ACh-ase, acetylcholinesterase; M, muscarinic receptor; N, nicotinic receptor; NE, norepinephrine.)

Causative Agents

Anticholinesterase insecticides include organophosphate and carbamate insecticides. These insecticides are in widespread use throughout the world for eradication of insects in dwellings and crops. Carbamates typically are less potent and inactivate cholinesterase in a more reversible fashion through carbamylation compared with organophosphates.[76] The prototype anticholinesterase agent is the organophosphate, which is the focus of this discussion. Many organophosphates are used as pesticides (eg, dichlorovos, disulfoton, malathion, parathion, mevinphos, and phosmet), and several were specifically developed for use as potent chemical warfare agents and adapted as terrorist chemical weapons (see the section later in this chapter).[12,76] An anticholinesterase insecticide typically is stored in a garage, chemical storage area, or living area. Anticholinesterase agents also can be found in occupational (eg, pest exterminators) or agricultural (eg, crop dusters or farm workers) settings. These agents also have been used as a means for suicide or homicide.

Incidence

Anticholinesterase insecticides are among the most poisonous substances commonly used for pest control and are a frequent source of serious poisoning in children and adults in rural and urban settings. The 2019 AAPCC-NPDS report documented 3,258 nonfatal single-product exposures and 1 death and 28 severe cases from anticholinesterase insecticides alone or in combination with other pesticides, with 28% of exposures in children younger than 6 years.[3]

Risk Assessment

The triad of miosis, bronchial secretions, and muscle fasciculations should suggest the possibility of anticholinesterase insecticide poisoning and warrants a therapeutic trial of the antidote atropine. In cases of low-level exposure, failure to develop signs within 6 hours indicates a low likelihood of subsequent toxicity.[76] Ruling out other chemical exposures may be guided initially by symptoms at presentation.[11,12]

Although the lethal dose for parathion is approximately 4 mg/kg, as little as 10 to 20 mg can be lethal to an adult and 2 mg (0.1 mg/kg) to a child. Small children may be more susceptible to toxicity because less pesticide is required per body weight to produce toxicity.[76] Estimation of an exact dose is impossible in most cases of acute poisoning; thus, tabulated “toxic” doses generally are not helpful in assessing risk of toxicity. Generally, ingestion of a small mouthful (approximately 5 mL in adults) of the concentrated forms of an organophosphate intended to be diluted for commercial or agricultural use will produce serious, life-threatening toxicity, whereas a small mouthful of an already diluted household product, such as an aerosol insecticide for household use, typically does not produce serious toxic effects.[78]

Measurement of acetylcholinesterase activity at the neuronal synapse is not feasible clinically. Cholinesterase activity can be measured in the blood as the pseudocholinesterase (butyrylcholinesterase) activity of the plasma and acetylcholinesterase activity in the erythrocyte. Both cholinesterases will be depressed with anticholinesterase insecticide poisoning.[76,78] Severity can be estimated roughly by the extent of depressed activity in relation to the low end of normal values. Because there are several methods to measure and report cholinesterase activity, each laboratory's normal range must be considered. Clinical toxicity usually is seen only after a 50% reduction in enzyme activity, and severe toxicity typically is observed at levels 20% or less of the normal range.[77] The intrinsic activity of acetylcholinesterase may be depressed in some individuals, but the absence of any manifestations in most people does not permit recognition of the relative deficiency in the general population. Therapy should not be delayed pending laboratory confirmation when insecticide poisoning is clinically suspected. Based on a history of an exposure and presence of typical symptoms, anticholinesterase toxicity should be readily recognized.[11]

Management of Toxicity

At the scene of the incident, move the patient away from area containing the organophosphate and decontaminate affected body surfaces with conventional first aid measures (see Table e8-8). Remove all contaminated clothing. People handling the patient should wear gloves and aprons to protect themselves against contaminated clothing, skin, or gastric fluid of the patient.[76,78] Because many insecticides are dissolved in a hydrocarbon vehicle, there is an additional risk of pulmonary aspiration of the hydrocarbon leading to pneumonitis when ingested. The risks and benefits of gastric decontamination (eg, activated charcoal) should be considered carefully and should involve consultation with a poison control center or clinical/medical toxicologist. Symptomatic cases of anticholinesterase insecticide exposure typically are referred to an ED for evaluation and treatment.

If the poison has been ingested within 1 hour, gastric lavage may be considered and followed by the administration of activated charcoal. For the patient with large-surface skin contamination, contaminated clothing should be removed, and the patient washed with copious amounts of soap and water before he or she is transported and admitted to the ED or other patient care area. An alcohol wash may be useful for removing residual insecticide because of its lipophilic nature. A surgical scrub kit for the hands, feet, and nails may be useful for exposure to those areas. Supportive therapy should include maintenance of an airway (including bronchotracheal suctioning), provision of adequate ventilation, and establishment of an IV line.

Pharmacologic management of organophosphate intoxication relies on the administration of atropine and pralidoxime.[76,78] Atropine has no effect on inhibited cholinesterase, but it competitively blocks the actions of acetylcholine on cholinergic and some CNS receptors. It thereby alleviates bronchospasm and reduces bronchial secretions. Although atropine has little effect on the flaccid muscle paralysis or the central respiratory failure of severe poisoning, it is indicated in all symptomatic patients and can be used as a diagnostic aid. It should be given IV and in larger than conventional doses of 0.05 to 0.1 mg/kg in children younger than 12 years and 2 to 5 mg in adolescents and young adults.[78] It should be repeated at 5- to 10-minute intervals until bronchial secretions and pulmonary rales resolve. Some recommend aggressive escalation of doses (eg, doubling of each successive dose) in cases with severe toxicity.[79] Therapy may require large doses over a period of several days until all absorbed organophosphate is metabolized, and acetylcholinesterase activity is restored.

Restoration of enzyme activity is necessary for severe poisoning, characterized by a reduction of cholinesterase activity to less than 20% of normal, profound weakness, and respiratory distress. Pralidoxime (Protopam), also called 2-PAM or 2-pyridine aldoximemethiodide, breaks the covalent bond between the cholinesterase and organophosphate and regenerates enzyme activity. Organophosphate-cholinesterase binding is reversible initially, but it gradually becomes irreversible in a process referred to as "aging." Therefore, therapy with pralidoxime should be initiated as soon as possible, preferably within 36 to 72 hours of exposure.[78] The drug should be given at a dose of 25 to 50 mg/kg up to 1 to 2 g IV over 5 to 20 minutes. If muscle weakness persists or recurs, the dose can be repeated after 1 hour and again if needed. A continuous infusion of pralidoxime is effective in adults when administered at 2 to 4 mg/kg/hr preceded by a loading dose of 4 to 5 mg/kg[80] and in children at 10 to 20 mg/kg/hr with a loading dose of 15 to 50 mg/kg.[81] Both atropine and pralidoxime should be given together because they have complementary actions (Table e8-12). Carbamate insecticide poisonings typically do not require the administration of pralidoxime.

TABLE e8-12

Comparative Characteristics of Atropine and Pralidoxime for Anticholinesterase Poisoning

Characteristic	Atropine	Pralidoxime
Interaction	Synergy with pralidoxime	Reduces atropine dose requirement
Indication	Any anticholinesterase agent	Typically needed for organophosphates
Primary sites of action	Muscarinic, CNS	Nicotinic > muscarinic > CNS
Adverse effects	Coma, hallucinations, tachycardia	Dizziness, diplopia, tachycardia, headache
Daily dose[a]	2-1,600 mg	1-12 g
Total dose[a]	2-11,422 mg	1-92 g

[a] Range of reported cases; higher doses may be required in rare cases.

One of the pitfalls of therapy is the delay in administering sufficient doses of atropine or pralidoxime.[76,79] The adverse effects of atropine and pralidoxime, which can be minimized by decreasing the dose, are predictable extensions of their anticholinergic actions and are minimally important compared with the life-threatening effects of severe anticholinesterase poisoning.

Monitoring and Prevention

Poisoned patients may require monitoring of vital signs, measurement of ventilatory adequacy such as blood gases and pulse oximetry, leukocyte count with differential to assess development of pneumonia, and chest radiographs to assess the degree of pulmonary edema or development of hydrocarbon pneumonitis. Workers involved in the formulation and application of pesticides should be monitored by periodic measurement of cholinesterase activity in their bloodstream. Untreated, acetylcholinesterase activity returns to normal values in approximately 120 days. Long-term follow-up for severe cases of poisoning may be necessary to detect the presence of delayed or persistent neuropsychiatric effects.

Many anticholinesterase insecticide poisonings are unintentional as a consequence of misuse, improper storage, failure to follow instructions for mixing or application, or inability to read directions for use. Training and vigilant adherence to directions may minimize some poisonings. Storing pesticides in original or labeled containers can minimize the risk of unintentional ingestion. Keeping pesticides out of children's reach may decrease the risk of childhood poisoning.[82]

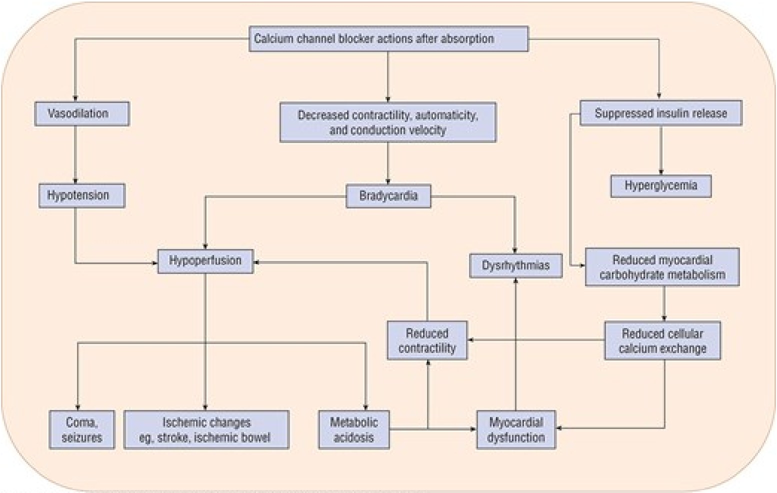
Calcium Channel Blockers

Clinical Presentation

⑧ Overdosage with calcium channel blockers typically results in bradycardia and hypotension (Fig. e8-4). Some patients become lethargic and may develop agitation and coma, but interestingly, in many cases mental status is preserved until patients are very ill. If the degree of hypotension becomes severe or is prolonged, the secondary effects of seizures, coma, and metabolic acidosis usually develop. Pulmonary edema, nausea and vomiting, and hyperglycemia are frequent complications of calcium channel blocker overdoses. Paralytic ileus, mesenteric ischemia, and colonic infarction have been observed in patients with severe hypotension. Many symptoms manifest within 1 to 2 hours of ingestion, butif a sustained-release formulation is involved, the onset of overt toxicity may be delayed by 6 to 18 hours from the time of ingestion. Severe poisoning can result in refractory shock and cardiac arrest. Death can occur within 3 to 4 hours of ingestion.[83–86]

FIGURE e8-4

Pathophysiologic changes associated with calcium channel blocker poisoning.



Calcium channel blocker actions after absorption
Vasodilation
Decreased contractility, automaticity, and conduction velocity
Suppressed insulin release
Hypotension
Bradycardia
Hyperglycemia
Hypoperfusion
Dysrhythmias
Reduced myocardial carbohydrate metabolism
Reduced contractility
Reduced cellular calcium exchange
Coma, seizures
Ischemic changes eg, stroke, ischemic bowel
Metabolic acidosis
Myocardial dysfunction

Mechanism of Toxicity

Most toxic effects of calcium channel blockers result from three basic actions on the cardiovascular system: vasodilation through relaxation of smooth muscles, decreased contractility by action on cardiac tissue, and decreased automaticity and conduction velocity through slow recovery of calcium channels. Calcium channel blockers interfere with calcium entry by inhibiting one or more of the several types of calcium channels and binding at one or more cellular binding sites. Selectivity of these actions varies with the calcium channel blocker and provides some therapeutic distinctions, but these differences are less clear with overdosage.[86] Although verapamil is most specific to the myocardial receptors (followed by diltiazem and then the dihydropyridines), signs and symptoms of overdose are similar among all drugs in this class due to the loss of selectivity.[87] Calcium channel blockers also inhibit insulin secretion, which results in hyperglycemia and changes in fatty acid oxidation in the myocardium that alter myocardial calcium flow and reduce contractility.[88] In fact, the degree of hyperglycemica may correlate with severity of toxicity.

CLINICAL PRESENTATION Calcium Channel Blocker Poisoning

General

- Life-threatening cardiac toxicity (bradycardia, depressed contractility, and dysrhythmias) within 1 to 3 hours of ingestion, delayed by 12 to 18 hours if a sustained-release product is involved.

Symptoms

- Nausea and vomiting within 1 hour.
- Dizziness, lethargy, and coma within 1 to 3 hours (mental status may be preserved in absence of significant hypotension).

Signs

- Hypotension and bradycardia within 1 to 6 hours.
- Unresponsiveness and depressed reflexes within 1 to 6 hours.
- Atrioventricular block, intraventricular conduction defects, and ventricular dysrhythmias on ECG.

Laboratory Tests

- Significant hyperglycemia (greater than 250 mg/dL [13.9 mmol/L]) may indicate severe toxicity and consideration for aggressive therapy.
- Altered blood gases (metabolic acidosis), serum electrolytes, lactic acid, BUN, and serum creatinine in response to shock within 1 to 6 hours.

Other Diagnostic Tests

- ECG with continuous monitoring and pulse oximetry to monitor for toxicity and shock.
- Monitor for complications of pulmonary aspiration such as hypoxia and pneumonia by physical findings and chest radiographs.

Causative Agents

Several calcium channel blockers are marketed in the United States for treatment of hypertension, certain dysrhythmias, and some forms of angina. The calcium channel blockers are classified by their chemical structure as phenylalkylamines (eg, verapamil), benzothiazepines (eg, diltiazem), and dihydropyridines (eg, amlodipine, clevidipine, felodipine, isradipine, nicardipine, nifedipine, and nimodipine). Several of these drugs, including diltiazem, nifedipine, and verapamil, are formulated as sustained-release oral dosage forms or have a slow onset of action and longer half-life (eg, amlodipine), allowing once-daily administration.

Incidence

In 2019, the AAPCC-NPDS report documented 6,020 nonfatal single-product toxic exposures to a calcium channel blocker; 111 patients exhibited and survived major toxic effects, and 31 died.[3]

Risk Assessment

Ingestion of an amount that exceeds the usual maximum single therapeutic dose or a dose equal to or greater than the lowest reported toxic dose (whichever is less) warrants referral to a poison control center and/or an ED. The threshold doses of several agents and dosage forms vary (eg, diltiazem: adults, greater than 120 mg for immediate release and chewed sustained release, greater than 360 mg for sustained release, greater than 540 mg for extended release; children younger than 6 years: >1 mg/kg).[89] Patients on chronic therapy with these agents who acutely ingest an overdose may have a greater risk of serious toxicity. Elderly patients and those with underlying cardiac disease may not tolerate mild hypotension or bradycardia. Concurrent ingestion of β-adrenergic blocking drugs, digoxin, class I antidysrhythmics, and other vasodilators may worsen the cardiovascular effects of calcium channel blockers.[84,86,89] The presence of persistent and significant hyperglycemia (>250 mg/dL [13.9 mmol/L]) may be a sign of grossly disturbed cardiac metabolism and physiology that merits attention and aggressive intervention.[88]

Management of Toxicity

There is no accepted specific prehospital care for calcium channel blocker poisoning, except to summon an ambulance for symptomatic patients.[90] The therapeutic options for management of calcium channel blocker poisoning include supportive care, gastric decontamination, and adjunctive therapy for the cardiovascular and metabolic effects. Supportive care consists of airway protection, ventilatory support, IV hydration to maintain adequate urine output, and maintenance of electrolyte and acid-base balance. Maintaining vital organ perfusion is critical for successful therapy to allow time for calcium channel blocker toxicity to resolve.[85,86]

A single dose of activated charcoal should be considered if instituted generally within 1 to 2 hours after ingestion. Besides exhibiting a slower onset of symptoms, sustained-release formulations can form concretions in the intestine.[85,86] Whole-bowel irrigation with polyethylene glycol electrolyte solution may accelerate intestinal elimination of the sustained-release tablets and should be considered for ingestions of sustained-release calcium channel blocker formulations. However, it should be used with caution if hemodynamic instability is present.[33] Adjunctive therapy is focused on treating hypotension, bradycardia, and resulting shock. Hypotension is treated primarily by correction of coexisting dysrhythmias (eg, bradycardia, heart block) and implementation of conventional measures to treat decreased blood pressure. Infusion of IV fluids and placement of central and arterial catheters are initial therapies for resuscitation and intensive monitoring. Further fluid therapy should be guided by bedside cardiac ultrasound as the poisoned heart may not be able to handle an excessive volume.[91] If hypotension persists, dysrhythmias are present, or other signs of serious toxicity are present, more specific therapy is indicated.[47,48,83] First-line therapies include IV calcium, norepinephrine and/or epinephrine, and high-dose insulin. Dobutamine, atropine, and lipid emulsion therapy may be considered. Interventions with the strongest level of evidence are high-dose insulin and extracorporeal life support.[83] Glucagon is no longer recommended for calcium channel blocker overdose but may still be helpful in beta blocker poisoning.[83]

Calcium IV is usually given first (or concomitant with early fluid resuscitation), in part because it is quick to administer and readily available with little preparation. Either calcium chloride or calcium gluconate is acceptable, if an equivalent amount of elemental calcium is provided (calcium chloride 1 g = calcium gluconate 3 g). In adults, calcium gluconate 2 g can be diluted in 100 mL normal saline and infused over 5 minutes through a peripheral line. If a positive cardiovascular response is achieved, the dose may be repeated every 30 minutes or a continuous infusion may be initiated. If multiple doses or a continuous infusion of calcium are administered, frequent laboratory monitoring is necessary to avoid clinically significant hypercalcemia. If calcium chloride is used, institutions vary on how dilute it should be to administer in a peripheral vein. One advantage of calcium gluconate is that it is less irritating and can be given peripherally. Central access is sometimes challenging in emergency scenarios and may take 10 to 15 minutes to secure. Calcium gluconate can infuse while central access is obtained. Atropine also may be considered for treatment of bradycardia, but it is seldom enough as a sole therapy.[83] Norepinephrine is the first vasopressor to initiate, with epinephrine, and/or dobutamine as additional options.[83] Higher than usual doses may be needed.[90]

For severe cases of calcium channel blocker toxicity refractory to fluids, calcium, and initial vasopressor doses, an infusion of high-dose insulin to produce a state of hyperinsulinemia and euglycemia should be initiated.[43,92] In the nonstressed state, the heart primarily catabolizes free fatty acids for its energy needs, while the stressed myocardium switches preference to carbohydrates. Insulin's positive inotropic effects seem to occur because of metabolic support of the heart during hypodynamic shock.[93] An IV bolus of regular insulin (0.5-1 units/kg) with 50 mL dextrose 50% (0.25 mg/kg for children) followed by a continuous infusion of regular insulin (0.5-1 units/kg/hr) may improve myocardial contractility.[94] This insulin regimen is titrated to improvement in systolic blood pressure over 100 mm Hg and heart rate over 50 beats/min. Serum glucose concentrations should be monitored closely. Supplemental glucose will be necessary in most patients but recall that hyperglycemia is a consequence of the poisoning. So, the amount needed will vary. Patients with serum potassium concentrations less than 3.5 mEq/L (mmol/L) will need supplemental potassium IV (see Chapter 70). The insulin infusion rate can be reduced gradually as signs of toxicity resolve. Glucose supplementation may be needed up to 24 hours after discontinuation of the insulin infusion.

Initiation of high-dose insulin therapy presents unique challenges. In an individual institution, it may be rare to encounter this therapy, meaning it might not be familiar to physicians, nurses, pharmacists, and other clinicians. There is often resistance because the dose is 10 to 100 times higher than what is used for other indications (eg, diabetic ketoacidosis). Recurrent education is important to inform all team members of the plan and purpose. Protocols and electronic order sets may facilitate safe and efficient administration. In addition, a standard insulin infusion is 1 unit/mL. A 70-kg patient receiving 5 units/kg/hr will use 350 mL/hr. This much fluid may be harmful in some patients and IV bags would need frequent preparation, straining resources. However, insulin is a high-risk medication in terms of safety, so simply having a more concentrated infusion for this one indication may also cause problems. Some centers use alternative concentrations such as 10 or 16 units/mL specifically for this indication.[95] Having the unique concentrations built into smart pump libraries also reduces the risk of error.

Intravenous lipid emulsion has the potential to rapidly reverse the severe cardiac toxicity of calcium channel blockers, though it has not been consistently demonstrated.[42,43,96] It can be considered in refractory cases. A reasonable dose for oral poisonings is 20% lipid emulsion as a 1.5 mL/kg bolus, followed by 0.25 mL/kg/min for 3 min, followed by 0.025 mL/kg/min up to 6.5 h.[78,97] Possible adverse effects include acute lung injury, pancreatitis, allergic reaction, fat emboli, and deep vein thrombosis.[79,98] Laboratory interference and incompatibility with other resuscitation medications are important logistical factors.[99–101] Blood specimens for labs should be drawn before lipid is given, if possible, and it should be administered in its own IV line. Lipid can also interfere with extracorporeal treatments.[82,102]

Several lifesaving options may be warranted for patients with cardiogenic shock that is refractory to conventional therapy, such as electrical cardiac pacing, intra-aortic balloon counterpulsation, or cardiopulmonary bypass. Measures to enhance elimination from the bloodstream by hemodialysis or multiple-dose activated charcoal are not effective and are not indicated for calcium channel blocker poisoning.[32,37,69,71,84,86] Venoarterial extracorporeal membrane oxygenation (ECMO) is available at some centers and is sometimes utilized in poisoned patients.[83,103,104] The circuit pumps blood from the venous side to the arterial side, while essentially removing the sick heart from the equation. Gas exchange and hemodynamic support are provided via ECMO until the heart recovers.[83]

Monitoring and Prevention

Regular monitoring of vital signs and ECG is essential in suspected calcium channel blocker poisoning. Determinations of serum electrolytes and lactic acid, serum glucose, blood gases (venous sampling is sufficient in most clinical scenarios), urine output, and kidney function are indicated to assess and monitor symptomatic patients. If serious toxicity is likely to develop, overt symptoms will manifest within 6 hours of ingestion.[73,89] For ingestions of sustained-release products in toxic doses, observation for 24 hours in a critical care unit may be prudent because the onset of symptoms may be slow and delayed up to 12 to 18 hours after ingestion.[68,73,83,89] Serum concentrations of these drugs in overdose patients do not correlate well with the ingested dose, degree of toxicity, or outcome.

Calcium channel blocker poisoning may be the result of an intentional suicide or unintentional ingestion by young children. Prevention of calcium channel blocker poisonings in children rests with the education of patients receiving these agents, particularly individuals who have children visit their homes infrequently, of their dangers on overdosage. Safe storage and use of child-resistant closures may reduce the opportunities for unintentional poisonings by children.

Anticholinergics

Clinical Presentation

Anticholinergic toxicity may present with peripheral and/or central findings. Peripheral anticholinergic effects include elevated body temperature, dry mucous membranes, flushed appearance, mydriasis that is minimally responsive to light, blurred vision, photophobia, tachycardia, urinary retention, and decreased bowel sounds.[11] Central findings include delirium, agitation, confusion, restlessness, visual or auditory hallucinations, seizures, or picking at imaginary objects.[11,105] CNS findings may persist longer than the peripheral findings; however, it is uncommon for patients to only experience central anticholinergic toxic effects.[106] Severe toxicity can manifest as seizures, cardiac conduction abnormalities (eg, QRS widening or increased QTc interval) with or without dysrhythmias, hypotension, or rhabdomyolysis.[107–109] The mnemonic “hot as a hare” (fever), “red as a beet” (flushed skin), “blind as a bat” (mydriasis), “dry as a bone” (dry mouth, decreased sweating), “mad as a hatter” (delirium), and “full as a flask” (urinary retention) can be helpful for remembering the anticholinergic toxidrome.

Mechanism of Toxicity

Anticholinergic agents are competitive antagonists of acetylcholine at the muscarinic receptors.[11,110] There are at least five muscarinic receptors (M1-M5), and the location of these receptors influences the clinical features of the anticholinergic toxidrome.[105,110] Competitive antagonism at the muscarinic receptor sites found in the smooth muscles, secretory glands, sweat glands, and eye ciliary leads to the peripheral anticholinergic effects, while the antagonism of acetylcholine at the central muscarinic receptors results in the CNS effects.[110] Pharmacologic agents commonly have other mechanisms of action and toxicity in addition to their anticholinergic properties,[111] which leads to the anticholinergic effects serving as either the primary (eg, diphenhydramine, dimenhydrinate, cetirizine) or secondary (eg, tricyclic antidepressants) source of toxicity.[112,113]

CLINICAL PRESENTATION Acute Anticholinergic Poisoning

General

- Multiple medications and plant species have anticholinergic properties, which can result in toxicity due to overdose as well as drug interactions

Symptoms

- Dry mouth, blurred vision, photophobia, or dry skin may occur within 6 to 8 hours of ingestion Delirium with or without hallucinations, confusion, agitation, or seizures may occur within 6 to 8 hours of ingestion

Signs

- Tachycardia, elevated body temperature, absent or decreased bowel sounds, dilated pupils minimally responsive to light Hemodynamic instability is less likely to occur, but may be seen with medications that have anticholinergic properties in addition to other mechanisms of action (eg, tricyclic antidepressants, quetiapine)

Laboratory Tests

- Due to combination products containing both acetaminophen and anticholinergic agents, obtain a toxic serum acetaminophen concentration no earlier than 4 hours after ingestion by comparison with nomogram Creatine kinase, serum electrolytes, and serum creatinine to assess for rhabdomyolysis and acute kidney injury

Other Diagnostic Tests

- ECG with continuous monitoring and pulse oximetry to monitor for toxicity Bladder scan for detection of urinary retention

Causative Agents

More than 600 unique pharmaceutical and herbal compounds can cause anticholinergic effects through their ability to inhibit the binding of acetylcholine to the muscarinic acetylcholine receptors.[111] The majority of these agents are ingested orally, though there are reports of anticholinergic toxicity due to adulterated drugs of abuse such as cocaine or heroin, which may be administered via injection, insufflation, or inhalation.[114,115]

Medications classes with anticholinergic properties include tricyclic antidepressants (eg, amitriptyline, nortriptyline, doxepin), selective serotonin reuptake inhibitors (eg, paroxetine, fluoxetine, citalopram), antihistamines (eg, diphenhydramine, doxylamine, cetirizine, loratadine, hydroxyzine), antiparkinson drugs (eg, benztropine, trihexyphenidyl), antipsychotics (eg, haloperidol, quetiapine, olanzapine), antispasmodics (eg, oxybutynin, tolterodine), antitussives (eg, dextromethorphan), belladonna alkaloids (eg, scopolamine, hyoscyamine), inhaled bronchodilators (eg, ipratropium, tiotropium), mydriatics (eg, atropine, cyclopentolate), and antiepileptics (eg, carbamazepine, oxcarbazepine) among others. The anticholinergic activity may be exerted through the medication's primary or secondary pharmacologic activity. Even in the therapeutic setting, co-ingestion of multiple medications with anticholinergic effects can have a synergistic effect on toxicity, which is particularly important in the elderly.[116] Antihistamines and decongestants are increasingly misused by adolescents and young adults seeking euphoric effects through "legal highs."[117]

Plants such as jimson weed (*Datura stramonium*), angel's trumpet (*Datura stramonium*), and nightshade (*Atropa belladonna*) contain potent alkaloids including atropine, hyoscyamine, and scopolamine.[118–120] There are reports of anticholinergic toxicity following recreational use of jimson weed and Angel's trumpet in pursuit of their hallucinogenic properties.[119,120] Teas brewed from anticholinergic plants are also associated with causing toxicity.[121]

Incidence

Anticholinergic toxicity commonly occurs due to drug interactions, intentional ingestions, accidental ingestions, and misuse of medications or plants in the pursuit of a "legal high."[3,117] According to the 2019 AAPCC-NPDS annual report, there were over 200,000 calls to poison control centers about exposures to pharmaceutical classes of medications with anticholinergic properties (eg, 137,881 calls for antidepressant exposures; 112,819 calls for antihistamine exposures). Over the last decade, the 2019 AAPCC-NPDS determined that antihistamines had the second for greatest rate of exposure increase. Anticholinergic medication classes also occupied several of the spots in the top 25 categories with the largest number of fatalities reported to AAPCC-NPDS in 2019.[3] Up to 20% of hospital admissions may be caused by anticholinergic delirium.[122]

Risk Assessment

Anticholinergic toxicity is a clinical diagnosis and should be suspected when patients present with symptoms consistent with the anticholinergic toxidrome.[111] Multiple individual medications with anticholinergic properties have established thresholds for toxicity.[112,113,123,124] Sedating, first-generation antihistamines have greater potential for toxicity than non-sedating, second-generation antihistamines.[112,124] Thus exposures to less than 7.5 mg/kg of diphenhydramine or 300 mg of dimenhydrinate, which are both first-generation antihistamines, are unlikely to cause significant toxicity. This allows for asymptomatic pediatric patients with accidental exposures to be monitored at home.[112] Patient age and routine, home medications influence the toxic potential of atypical antipsychotic medications. Specifically, patients that are less than 12 years old and naïve to atypical antipsychotics may experience moderate toxicity following an ingestion of 4 or more times the initial atypical antipsychotic starting dose in an adult (ie, aripiprazole 15 mg, clozapine 50 mg, olanzapine 10 mg). While, patients age 12 years and older that are naïve to atypical antipsychotic medications, may experience moderate toxicity following an ingestion of 5 or more times the initial atypical antipsychotic starting dose in an adult. Those chronically on atypical antipsychotics are unlikely to experience significant toxicity following an acute ingestion of less than five times their current single dose.[123] TCAs have a narrow therapeutic index and their sodium channel blocking effects can cause profound cardiac toxicity in addition to anticholinergic effects. In children less than 2 years old, an exposure to as little as one pill can result in significant morbidity ("one pill can kill" medication).[125,126] In older patients, an accidental ingestion of greater than 5 mg/kg of amitriptyline or 2.5 mg/kg of nortriptyline would necessitate an evaluation in the ED.[113] Unless a patient was exposed to a sustained release product, significant toxicity will manifest within 6 to 8 hours of the exposure if it is to occur at all.[105,112,113,123]

Management of Toxicity

The treatment strategies differ depending on the severity of anticholinergic toxicity and agent(s) involved. Supportive care with an emphasis on maintaining the patient's airway, breathing, and circulation is part of standard care for patients with mild to severe anticholinergic toxicity. IV fluid resuscitation is utilized to correct the state of dehydration, provide hemodynamic support, and treat rhabdomyolysis. Benzodiazepines may be utilized for the treatment of seizures or agitation. Sodium bicarbonate boluses of 1 to 2 mEq/kg (mmol/kg) IV followed by continuous infusions run at 1.5 to 2 times the maintenance fluid rate can be used to reverse wide complex dysrhythmias.[127,128] Antidysrhythmic agents like lidocaine and vasopressors may be utilized to treat dysrhythmias and hypotension unresponsive to IV fluids, respectively. At least one IV access should be obtained. Following the obtainment of a baseline ECG, the clinical condition of the patient will drive the need for continuous cardiac monitoring, continuous pulse oximetry, and supplemental oxygen. GI decontamination with activated charcoal may be considered in patients who are not at risk of aspiration and present within 1 to 2 hours of ingestion.[30,129,130]

Physostigmine is a carbamate acetylcholinesterase inhibitor which can reverse both the central and peripheral manifestations of anticholinergic toxicity. Toxicologists have variable practices for when they recommend its use,[131] but it is typically reserved for the management of moderate-to-severe anticholinergic toxicity.[106,122,131–134] Physostigmine is more effective than benzodiazepines in controlling agitation and reversing delirium associated with anticholinergic toxicity, which leads to a shorter time to recovery.[106,122,133,135] When compared to patients receiving benzodiazepines, those receiving physostigmine have had lower rates of complications related to anticholinergic toxicity including sedation, aspiration, and intubation.[106]

Historically, physostigmine was associated with severe adverse effects, which have limited its widespread use. Specifically, there are three case reports of cardiac arrest following physostigmine administration in patients with tricyclic antidepressant overdoses experiencing severe cardiotoxicity including hypotension and wide complex dysrhythmias.[136,137] These cases occurred before sodium bicarbonate therapy was widely incorporated as the antidote for tricyclic antidepressant overdoses, so the lack of sodium bicarbonate antidote administration could have also contributed to the cardiac arrests.[113,128,136–138] More recent studies suggest that physostigmine rarely causes the significant adverse effects of bradycardia, bradydysrhythmias, or seizures.[106,122,133–135,139]

Due to its potential for serious adverse, patients are carefully assessed to determine if benefits of physostigmine administration outweigh the risks.[106,122,135] As a result, it is typically reserved for the treatment of moderate-to-severe anticholinergic toxicity and avoided in patients known or suspected to have a tricyclic antidepressant toxicity.[131,139] Before physostigmine administration, an ECG should be obtained to assess for widened QRS intervals greater than 100 to 120 ms,[122] which could suggest tricyclic antidepressant involvement.[140] At the time of physostigmine administration, patients should be placed on continuous cardiac monitoring and have atropine readily available to reverse physostigmine-induced cholinergic effects of bradycardia or bronchorrhea. The recommended physostigmine dose for adult patients is 0.5 to 2 mg IV over at least 5 minutes.[106,122] Pediatric patients receive a weight based dose of 0.02 mg/kg IV over at least 5 minutes with a maximum dose of 0.5 mg.[122] Slow IV administration helps reduce the risk of rate-dependent adverse effects like bradycardia and seizures. Additional doses may be repeated every 10 to 15 minutes for inadequate response or recurrence of moderate-to-severe anticholinergic toxicity.[122] Physostigmine's 45 to 60 minute duration of action is often shorter than that of the offending agent, which necessitates repeat doses of physostigmine in approximately one third of patients.[132]

Monitoring and Prevention

Anticholinergic poisoning may be a result of intentional suicide, unintentional ingestions, or drug-drug interactions due to coadministration of multiple agents with anticholinergic properties. In patients presenting with features of the anticholinergic toxidrome, clinicians should physically examine patients for transdermal patches like scopolamine and remove them from the patient's body. Concealment of scopolamine transdermal patches by clothing can continue to exacerbate toxicity in addition to delay the recognition, identification, and management of anticholinergic toxicity.[141] Regular monitoring of vital signs and ECG is essential in suspected anticholinergic overdoses. Severe toxicity can manifest cardiotoxic effects such as dysrhythmias. Serum electrolytes, serum glucose, kidney function, CPK, and urine output aid in the assessment and monitoring of symptomatic patients. Bladder scans are beneficial to assess for urinary retention, which can exacerbate agitation. If serious toxicity is likely to develop, patients will exhibit peripheral or central anticholinergic effects within 6 hours of ingestion. Exposure to a sustained release product with anticholinergic properties may delay the development of symptoms by approximately 12 to 24 hours.

Polypharmacy is common in elderly patients.[142] Pharmacists can help prevent anticholinergic toxicity in this patient population through the review of patient home medications for opportunities to deprescribe anticholinergic medications.[116]

Opioids

Clinical Presentation

⑩ Acute opioid poisoning can produce life-threatening effects that typically include respiratory depression and coma that may lead to death.[143] Virtually all opioids produce these symptoms and some agents have additional toxic effects. The time of onset and severity of symptoms depend on the route of exposure, formulation of the drug product, potency of the opioid total dose received, concurrent drugs, coexisting conditions, and pharmacogenetic characteristics. Toxic signs and symptoms develop most rapidly after IV injection (within minutes) or inhalation of fumes (heroin), followed by inhalation from snorting particles, powder, or solutions. Immediate-release tablets typically have an onset of toxicity within 1 to 4 hours, followed by sustained-release tablets and dermal patches on the skin, which exhibit the slowest onset. Severe symptoms can occur from absorption by any route. Death typically is caused by respiratory failure, the metabolic consequences of hypoxia, noncardiogenic pulmonary edema and, in some cases, pulmonary aspiration of gastric contents after vomiting. Opioid poisoning may be complicated by hypothermia, rhabdomyolysis, and resultant acute kidney injury. Seizures, dysrhythmias, concurrent exposure to and toxicity from other medications and illicit drugs, and the presence of adulterants and contaminants may complicate the person's presentation. Finally, hepatotoxicity from the co-ingestion of acetaminophen-containing medications, and infectious diseases from IV drug use may occur.[143]

Mechanism of Toxicity

Action at the μ-opioid receptor is primarily responsible for many of the life-threatening effects of opioids, such as respiratory depression and sedation, and all opioid analgesics have some activity at this receptor. Meperidine's metabolite, normeperidine, produces CNS excitation that leads to delirium, tremor, and seizures. Meperidine also blocks the reuptake of serotonin and may produce serotonin syndrome particularly in patients taking monoamine oxidase inhibitors.[144] Methadone acts on the myocardium to block potassium efflux leading to dysrhythmias such as Torsades de pointes, syncope, and sudden death.[145] Tapentadol and tramadol block reuptake of norepinephrine and serotonin, respectively, and are associated with seizures.[143]

Causative Agents

Many opioid drugs are available in the United States for the management of moderate-to-severe pain (see Chapter 79). These include drugs that are naturally found in opium (ie, opiates such as morphine and codeine), synthetic opioids (eg, fentanyl, methadone, and meperidine), and semisynthetic opiate derivatives (eg, hydromorphone, hydrocodone, and oxycodone). Heroin is a schedule I controlled substance and illicit drug. It produces more euphoria than many other opioids and produces the same life-threatening effects with added complications of adulterants and infections from IV drug use. Chemical analogs of legitimate opioids such as fentanyl are produced by clandestine laboratories. Illicitly manufactured analogs often have much greater potency unbeknownst to the user and thus increase the risk of a lethal overdose.[146]

Incidence

Based on provisional estimates for 2017 approximately 49,000 Americans died from opioid overdoses, including analgesics, heroin and illicit synthetic opioids, which represents a 4.1-fold increase compared to 2002. Deaths related to fentanyl and fentanyl analogs accounted for the sharpest increase with nearly 30,000 deaths—a 22-fold increase compared to 2002. During this same period heroin-related deaths increased 7.6-fold with approximately 16,000 deaths in 2017. Prescription opioid pain relievers accounted for 17,087 deaths in 2016 which was a 2.6-fold increase compared to 2002.[147] Poisoning from opioids occurs in all age groups, from neonates through intrauterine exposure to the elderly, and in rural and urban areas. Poisoning can occur from a variety of circumstances such as the unintentional ingestion of medicines by young children. Inadvertent overdoses can occur in adolescents or adults from taking single or multiple "therapeutic" doses of opioids with several sedating drugs (particularly benzodiazepines). Using opioids to produce self-harm can end in suicide and abusing opioids as part of a substance use disorder may also lead to death. The 2019 AAPCC-NPDS report documented 21,211 nonfatal single-product exposures that were voluntarily reported to poison centers, 4,311 with severe symptoms, and 284 deaths from opioids alone; 55% of the cases were associated with intentional use and 14% of exposures occurred in children younger than 6 years of age.[3]

CLINICAL PRESENTATION: Acute Opioid Poisoning

General

- Life-threatening respiratory depression (12 or less breaths per minute) within minutes to hours of use depending upon the drug, route of administration, product formulation, and coexisting conditions; often delayed by 8 or more hours with ingestion of a sustained-release product.

Symptoms

- Lethargy progressing to coma.
- Flaccid extremities.
- Seizures associated with meperidine and tramadol.

- Acute muscular rigidity with rapid injection of fentanyl.
- Deafness with some overdoses.

Signs

- Depressed respiratory depth and rate leading to apnea.
- Pinpoint pupils (uncommon with meperidine, tramadol, and severe hypoxia).
- Unresponsiveness and depressed reflexes.
- Mild hypotension and bradycardia, worsening with increasing hypoxia.
- Absent bowel sounds, GI hypomotility.
- Hypothermia if exposed to cold conditions.
- Frothy pink sputum, end-inspiratory crackles on auscultation, and shortness of breath several hours after exposure consistent with pulmonary edema.
- QT-interval prolongation leading to Torsades de pointes on ECG with methadone.
- One or more opioid-containing drug patches (eg, fentanyl) on the skin.
- “Needle tracks” or skin infections if IV drug user.

Laboratory Tests

- Altered arterial blood gases (acidosis) and serum electrolytes in response to hypoxia.
- Serum glucose concentration.
- Determine serum acetaminophen concentration no earlier than 4 hours after ingestion and ALT in case an opioid-acetaminophen combination product ingested.

Other Diagnostic Tests

- Pulse oximetry and ECG with continuous monitoring.
- Monitor for complications of pulmonary aspiration such as hypoxia and pneumonitis by physical findings and chest radiographs.
- Monitor for complications of rhabdomyolysis (creatine kinase, electrolytes) and subsequent acute kidney injury (BUN, creatinine) if patient has been lying immobile for several hours.
- Evaluate for infectious diseases if IV drug use, and local- or systemic-infection suspected.

Risk Assessment

A patient’s symptoms, presence of drugs or substance abuse paraphernalia at the scene, and availability of opioids can be helpful indicators of risk. The triad of depressed respirations (12 or less breaths per minute), coma, and pinpoint pupils (miosis) with relatively acute onset should strongly suggest opioid poisoning and warrants a therapeutic trial of the antidote naloxone.[11,43,143] Clonidine and certain atypical antipsychotics (eg, olanzapine) may present similarly. Measurement of opioid serum concentrations are not available in clinical laboratories and are not necessary to guide appropriate therapy. Therapy should not be delayed pending laboratory confirmation of an opioid in a routine drug screen because many opioids are not detected (see Table e8-6) and critical time will be lost awaiting results that will not guide therapy.

Management of Toxicity

The foundation of treatment of opioid poisoning is adequate respiratory support and the administration of the opioid antagonist naloxone.[143] Symptomatic cases of opioid overdoses should be transported to an ED for evaluation and treatment. Naloxone is the primary treatment in the prehospital setting. In the current opioid epidemic, naloxone availability has increased and there is a focus on preparing family members, friends, and bystanders to respond to overdoses. The number of naloxone training programs has increased, and many states have made naloxone available without a prescription. The intranasal route is safest for bystanders and prehospital providers, and newer formulations of naloxone have made administration by this route even easier.

Activated charcoal is generally not administered to adult patients with suspected opioid overdose. However, for unintentional ingestions (eg, children), charcoal may be considered after weighing the risks of pulmonary aspiration (ie, if vomiting occurs in a patient with altered or worsening mental status), if the opioid has been ingested within 1 hour.[30,143] Based on a history of an exposure, presence of typical symptoms and the response to naloxone, an acute opioid poisoning should be recognizable in most cases. Whole bowel irrigation can be considered for ingestions of extended-release formulations, packets of drugs such as heroin intended for smuggling, and fentanyl dermal patches once the patient is stabilized.[33,34,143]

Naloxone is a competitive opioid receptor antagonist that acts on known opioid receptors to reverse the toxic effects of opioids (Table e8-13) and can be life-saving. The goal of therapy is to restore adequate spontaneous respirations. It is typically administered by rapid IV injection, acts within 2 minutes and has a short duration of action of 20 to 90 minutes.[43] Intramuscular, intraosseous, intralingual injection, intranasal, and intratracheal instillation are also effective if the IV route is not immediately available. Oral administration is ineffective for reversing CNS opioid intoxication due to its low bioavailability but can be used for opioid-induced ileus. Naloxone for injection is available in concentrations of 0.02, 0.4, and 1 mg/mL. The effect of naloxone may not be evident in several circumstances (see Table e8-13) and the initial dose may not be sufficient.

TABLE e8-13

Responses to Naloxone in Opioid Poisoning

Therapeutic Reversal of Toxicity	Factors for Poor or No Response
Respiratory depression	Polydrug overdose (eg, benzodiazepines, sedatives, muscle relaxants, ethanol)
CNS depression	Inadequate dose of naloxone
Miosis	Concurrent head injury
Cardiovascular depression	Hypoglycemia
Gastrointestinal hypomotility	Hypoxic state (CNS, acid/base disorders)
Euphoria	Postictal state
Dependence leading to withdrawal	No opioid involved

The dosing of naloxone should consider a balance of reversing toxic effects without causing abrupt withdrawal symptoms, which can produce agitation, hypertension, tachycardia, emesis with the risk of aspiration, and harm to the patient and caregivers from disorientation.[148] Intravenous dosage regimens have evolved from clinical experience and differ from the recommended starting dose of 0.4 to 2 mg in the package insert. A typical approach involves administering 0.04 to 0.05 mg (0.01 mg/kg in a young child) as the first IV dose. If there is no improvement in respirations within 2 minutes, 0.5 mg is administered to adults and children. At 2-minute intervals the dose can be increased to 2, 4, 10, and 15 mg until adequate respirations are achieved.[43,148] If there is no response at the 10 to 15 mg dose, confounding or other causes of the patient's condition should be considered. Other regimens with similar progressive increases in dose have been proposed. Overdoses with buprenorphine and methadone often require doses in the upper range for a response.[148] The duration of naloxone's effect is generally shorter than many opioids (usually 45-60 minutes), particularly for methadone and extended-release formulations, and requires close monitoring and repeated administration. If repeated doses of naloxone are required for maintenance of adequate respiration, a continuous infusion should be considered that is approximately two-thirds of the single-dose that produces a response given at an hourly rate.[43] The IM autoinjector delivers naloxone 2 mg per injection and the intranasal spray delivers 4 mg per use and are typically used for children and adults by first-responders and trained bystanders.

In patients with no opioid present, the adverse effects of large doses of naloxone are rare, minimal, and insignificant and it can be given safely to persons with acute poisonings of any cause. In opioid-dependent patients, however, hypertension, hyperventilation, and tachycardia can occur and may be related to the release of catecholamines and other mediators in response to stress from abrupt withdrawal.[148] Agitation, confusion, and vomiting are possible additional effects following naloxone administration. The progressive escalation of naloxone doses to prevent abrupt withdrawal is partially based on its potential association with acute lung injury that may produce or exacerbate pulmonary edema.[43,149]

Monitoring and Prevention

Poisoned patients may require monitoring of vital signs, ventilatory adequacy (ie, blood gases and pulse oximetry), and chest radiographs to assess the degree of pulmonary edema or development of aspiration pneumonitis. Patients should also be monitored for the potential development of complications such as rhabdomyolysis, acute kidney injury, or seizures. Determination of a serum acetaminophen concentration is warranted to rule out the coincidental ingestion of acetaminophen with an opioid-acetaminophen combination product.[143]

The rising number of deaths from prescription opioid analgesics has been categorized as an epidemic by the Centers for Disease Control and Prevention (CDC). Multiple strategies have been implemented and proposed to prevent opioid-related deaths.[150] A controlled substances monitoring database (also called a prescription drug monitoring program) has been implemented in nearly every state in order to identify individuals using frequent prescriptions of controlled substances from multiple prescribers ("doctor shopping") or fraudulent prescriptions.[151] Enforcement and implementation of laws on "doctor shopping," indiscriminate prescribing of controlled substances without a medical evaluation by "pill mills," and efforts to improve medical practice through educational programs and guidelines for the treatment of chronic pain are underway. The FDA implemented a Risk Evaluation and Mitigation Strategy for oral opioids that involve prescriber training on appropriate prescribing practices. "Drug take-back" events to dispose of unneeded medications have been conducted in communities nationwide. Reducing the availability of medications, particularly opioids, in the home reduces the opportunity for stealing and diverting medications that can lead to overdoses and drug abuse. Most states have enacted laws to allow intranasal or intramuscular administration of naloxone by trained bystanders and law enforcement officers in the community to opioid-dependent individuals and heroin abusers at risk for life-threatening overdose in order to prevent death before an ambulance arrives.[152] Education of the general public on the risks of opioid poisoning and appropriate use and storage of opioid analgesics should be a routine practice in the prescribing and dispensing of opioid analgesics.

Weapons of Mass Chemical Poisoning

Clinical Presentation

⑪ Most chemicals used in warfare or terrorist attacks act immediately upon contact with the skin, mucous membranes, or respiratory tract. The variety of potential agents has been generally categorized by the type of toxic action or target organ system (Table e8-14) that also reflects the anticipated signs and symptoms of poisoning. Typically, clusters of victims have similar presentation, but the extent and onset of injury depends upon the person's level of exposure, which is related to their proximity to the source of the chemical, the method of deployment (eg, vapor, liquid, gas, and aerosol explosive device) and the mechanism of toxicity of the chemical. Inhalational exposures to nerve agents or cyanide will produce symptoms and sometimes death within minutes of exposure; whereas, slower absorption with dermal contact will delay the onset. Agents such as sulfur mustard and phosgene may take 4 to 6 hours for onset of toxicity.[12] Some toxins of biologic origin, such as ricin, often require days to weeks for characteristic symptoms to develop due to the mechanism of action. Nerve agents are highly potent anticholinesterases that have the same pathogenesis of toxicity (see Fig. e8-2) and produce the full spectrum of signs and symptoms of organophosphate insecticides (see Table e8-14).[12,153] One of the several major differences between nerve agents and organophosphate insecticides is the hyperacute onset of life-threatening symptoms, such as fulminant respiratory failure within seconds to minutes with nerve agents.[12] Another difference is the extreme oculogyric torsion with nerve agents that may require administration of tropicamide ophthalmic drops to relieve eye pain. Moderate-to-severe poisonings from chemical warfare or terrorist agents will typically require care in an intensive care unit.[154]

TABLE e8-14

Categories of Chemicals of Mass Poisoning

Category and General Effects	Examples*
Biotoxins *(variety of toxicities from plant or animal origin)*	Ricin
Blister Agents/Vesicants *(severely blister the eyes, respiratory tract, and skin on contact)*	Mustards, sulfur mustard gas (H), lewisites (L), chloroarsine agents, phosgene oxime (CX)
Blood Agents *(interfere with the delivery and use of oxygen)*	Arsine (SA), carbon monoxide, cyanides, sodium monofluoroacetate
Choking/Lung/Pulmonary Agents *(cause severe irritation or swelling of the respiratory tract)*	Ammonia, chlorine, hydrogen chloride, methyl isocyanate, phosgene (CG), phosphine
Corrosives (Caustics, Acids) *(burn or corrode skin, eyes, and mucus membranes on contact)*	Hydrofluoric acid, hydrogen chloride, sulfuric acid
Incapacitating Agents *(cause an altered state of cognition and consciousness or unconsciousness)*	Fentanyl analogs and other opioids, "QNB" 3-quinuclidinyl benzilate (BZ)
Metals *(heavy metals that disrupt cellular function)*	Arsenic, mercury, thallium
Nerve Agents *(anticholinesterases that affect normal functioning of peripheral and central nervous systems)*	Novichok agents, Sarin (GB), soman (GD), tabun (GA), VX
Riot Control Agents/Tear Gas *(cause significant irritation of the eyes, skin, and airway)*	Bromobenzylcyanide (CA), chloroacetophenone (CN), chlorobenzylidenemalononitrile (CS), chloropicrin (PS), dibenzoxazepine (CR)
Vomiting Agents *(cause severe nausea and vomiting)*	Adamsite (DM)

*North Atlantic Treaty Organization (NATO) code in parentheses.

Data from Emergency Preparedness and Response: Chemical Emergencies.

Centers for Disease Control and Prevention. Atlanta, GA. November 25, 2014. http://emergency.cdc.gov/chemical/index.asp

Mechanism of Toxicity

There is no single unifying mechanism of toxicity of the chemicals used for warfare or terrorism because of the variety of different agents involved (see Table e8-14). The mechanism for nerve agents is well characterized by its anticholinesterase action (see earlier section on Anticholinesterase Insecticides).[76,153] Some agents act by an extreme exaggeration of their pharmacologic actions such as BZ producing extreme anticholinergic CNS effects and fentanyl analogs producing extreme opioid toxicity (see **CLINICAL PRESENTATION BOX** for acute opioid poisoning). Vesicants, such as sulfur mustard, irreversibly alkylate deoxyribonucleic acid (DNA), RNA and proteins and produce burns, blisters, and tissue destruction.[153] Blood agents act in several ways, but ultimately interfere with the transport or utilization of oxygen by cells. Cyanide, for example, is a potent competitive inhibitor of cytochrome oxidase and other enzymes and stops cellular respiration throughout the body.[12,153] Pulmonary agents, such as chlorine or phosgene, both react with water to produce hydrochloric acid, which produces severe irritation and destruction to mucosal tissue, ocular surfaces, the airway and lungs.[153]

Causative Agents

Many different chemicals have been used or have been recognized for their potential for terrorism or warfare (see Table e8-14). Adaptation of other commercial chemicals, synthesis of analogs of existing toxins, or creation of novel chemicals may introduce additional hazards in the future.

Incidence

The use of chemical weapons during the past century has been documented in numerous warfare and terrorism settings that produced mass casualties. For example, during World War I, 100,000 deaths and 1.2 million casualties were attributed to attacks with chlorine, phosgene or mustard.[155] In 1995, terrorists released sarin in the Tokyo subway system, leading to 11 deaths and 5,510 people seeking medical attention including many first-responders.[156,157] More recently, in the United Kingdom, a Novichok anticholinesterase agent was implicated in a 2018 assassination attempt of a former Russian spy and his adult daughter.[158]

Risk Assessment

Assessment of injuries at the scene, triage stations, and healthcare facilities should identify victims at greatest risk and priority for treatment. The acute onset of serious symptoms in many victims without signs of trauma suggests a mass chemical exposure. Patients with typical clusters of symptoms, such as those associated with anticholinesterase agents, may provide clues to the type of chemical and guide treatment.[12,159]

Management of Toxicity

High priorities for managing exposures to chemical warfare or terrorism agents are to evacuate victims from the contaminated area, decontaminate any exposed surfaces with first aid measures (see Table e8-8), and removal of contaminated clothing.[159] First-responders should guard against being poisoned by wearing personal protective equipment, such as body suits, gloves, boots and air supply, as appropriate for the situation. Supportive and symptomatic care with attention to airway, breathing and circulation are critical for all types of exposures and may be the extent of treatment options useful for a toxin.[12,154,159,160] Most chemicals associated with mass poisoning exposures do not have a specific therapy or antidote. Several toxins, such as nerve agents, opioids, and cyanides, do have specific antidotes that may be life-saving (see Table e8-9). The sooner therapy can be instituted in the field, as in carrying atropine, pralidoxime, and diazepam autoinjectors in an area where a nerve agent attack is anticipated, generally the better the outcome will be. Depending upon the conditions, additional decontamination before a victim enters a healthcare facility may be necessary to avoid contaminating healthcare workers and other patients in the treatment area. Guidance on treatment for a specific chemical exposure is available at several Websites of the Centers for Disease Control and Prevention (CDC) (http://emergency.cdc.gov/chemical/index.asp; www.cdc.gov/NIOSH/ershdb/default.html; www.atsdr.cdc.gov).

Monitoring and Prevention

Survivors of a chemical attack may develop long-term effects or life-long disabilities.[161] For example, vesicants have been associated with cancer, severe burns, and scars; pulmonary agents may produce permanent respiratory conditions; and nerve agents may lead to short- and long-term neuromuscular disabilities. Victims of any mass poisoning are at risk for developing psychological distress after the attack and warrant follow-up once the acute medical condition is stabilized.

Prevention of chemical attacks is beyond the scope of healthcare professionals' standard responsibilities; however, preparation for mass chemical emergencies is a vital element of mass casualty preparedness. Working with local health department representatives, safety officials and other healthcare professionals to develop a community plan is important because no single site can likely provide the necessary resources to treat the number of victims. The CDC has resources that provide guidance on medical management of chemical hazards (http://emergency.cdc.gov/agent/agentlistchem.asp), healthcare preparedness and response (https://www.cdc.gov/phpr/readiness/healthcare/index.htm), and access to the Strategic National Stockpile (http://www.cdc.gov/phpr/stockpile/stockpile.htm) among other areas of interest.

ABBREVIATIONS

AAPCC-NPDS	American Association of Poison Control Centers—National Poison Data System
ALT	alanine aminotransferase
AST	aspartate aminotransferase
BUN	blood urea nitrogen
BZ	3-quinuclidinyl benzilate
CDC	Centers for Disease Control and Prevention
CNS	central nervous system
CVVH	continuous veno-venous hemofiltration
CYP	cytochrome P450
DNA	deoxyribonucleic acid
ECG	electrocardiogram
ED	emergency department
ECMO	extracorporeal membrane oxygenation
Fab	fragment antigen binding
FDA	Food and Drug Administration
GI	gastrointestinal
IV	intravenous
INR	international normalized ratio
NAPQI	*N*-acetyl-*p*-benzoquinoneimine
PPPA	Poison Prevention Packaging Act of 1970
RNA	ribonucleic acid

SELF-ASSESSMENT QUESTIONS

1. Which of the following statements are true characterizations of poisonings in children and adults?

    A. Medicines are the most common cause of poisoning in adults and children.

B. More children die from poisonings than adults.

C. Only adults may act purposefully or with obvious intent to ingest a substance that may be poisonous.

D. Only children may not recognize a product's risk for poisoning.

2. Which one of these examples of first aid for poisoning is correct?

A. Immediately rinse the eye with sterile water when a chemical is splashed on it.

B. For an ingested poison, 2-4 ounces (60-120 mL) of water can be given unless the person is unconscious, having convulsions, or cannot swallow.

C. Contact a poison control center after symptoms develop.

D. Inhaled poisons typically cannot penetrate a handkerchief over the nostrils so that it can be used to protect against fumes in order to rescue someone.

3. In which of the following circumstances should the particular form of gastric decontamination be used for a person who swallowed something that could be poisonous?

A. Gastric lavage should be used routinely for those who have ingested a liquid or small tablet.

B. Single-dose activated charcoal should be considered for most ingestions if contraindications are not present.

C. Whole bowel irrigation should be started for any ingestion of a plant, foreign body, or large tablet.

D. A cathartic such as magnesium citrate should be administered for all ingestions.

4. A 24-year-old woman who has acutely ingested immediate-release acetaminophen tablets 10 hours ago has a serum acetaminophen concentration of 100 μg/mL (660 μmol/L). Her only complaint is nausea and she has vomited several times in the past 2 hours. No other drugs are suspected. Which of the following would be appropriate?

A. Repeat the serum concentration and wait 2 hours for the results

B. Administer activated charcoal orally

C. Begin therapy with intravenous acetylcysteine

D. Begin therapy with oral acetylcysteine

5. Which of the following is a potential advantage of the intravenous formulation of acetylcysteine compared to the oral formulation?

A. Medication administration errors are infrequent with the intravenous formulation.

B. The duration of therapy is shorter with the intravenous formulation.

C. The total dose of acetylcysteine is greater with the intravenous formulation.

D. The systemic adverse effects are no different than those with the oral formulation.

6. What is the preferred treatment for a 55-year-old farmer who is exhibiting excessive bronchial and oronasal secretions following exposure to an organophosphate insecticide and is otherwise healthy?

A. Atropine intravenously

B. Diphenhydramine orally

C. Physostigmine intramuscularly

   D. Pralidoxime intramuscularly

7. Which of the following is true regarding the treatment of an organophosphate insecticide poisoning?

   A. Doses of atropine necessary to treat organophosphate poisoning are similar to those normally used to treat simple bradycardia in patients not poisoned with organophosphates.

   B. An endpoint of therapy with atropine is an acceptable heart rate.

   C. Excessive drying of bronchial secretions may contribute to death.

   D. An endpoint of therapy with pralidoxime is an improved and acceptable respiratory effort.

8. Which of the following is true regarding calcium channel antagonist overdose?

   A. The drugs in the chemical classes of calcium channel antagonists differ in their predominant toxicity upon overdose.

   B. Hypoglycemia occurs due to excess insulin release.

   C. Concurrent ingestion of beta adrenergic blockers or digoxin may worsen the cardiovascular toxicity.

   D. The onset of toxicity of immediate-release formulations is often delayed by 6 to 18 hours.

9. Beyond standard supportive care, what drug, given intravenously, is preferred as the first choice for bradycardia and hypotension from a calcium channel antagonist overdose?

   A. Calcium chloride

   B. Norepinephrine

   C. Atropine

   D. Lipid intravenous emulsion

10. Which of the following is true regarding the clinical presentation of anticholinergic toxicity?

   A. Coma, respiratory depression, miosis

   B. Hypotension, bradycardia, altered mental status, hypoglycemia

   C. Dry mucous membranes, urinary retention, mydriasis, tachycardia, delirium

   D. Diarrhea, urination, miosis, bronchospasm, bronchorrhea, bradycardia, emesis, lethargy, lacrimation, salivation

11. What is the treatment of choice for a 30-year-old male who overdosed on diphenhydramine and is now experiencing signs of severe anticholinergic toxicity including sinus tachycardia with ECG demonstrating a QRS of 80 ms, bladder scan demonstrating 500 mL of retained urine, and agitation?

   A. Pralidoxime intravenously

   B. Atropine intravenously

   C. Lorazepam intravenously

   D. Physostigmine intravenously

12. Which collection of sign and symptoms would suggest an acute overdose of an opioid?

A. Depressed respirations, miosis, and unresponsiveness

B. Hypotension, bradycardia, and hyperglycemia

C. Muscle fasciculations, miosis, and shortness of breath

D. Vomiting, diarrhea, and hypotension

13. Which of the following can be a factor in poor reversal of opioid toxicity by naloxone?

A. Gastrointestinal hypomotility

B. Hyperglycemia

C. Opioid dependence

D. Overdose with other drugs that have sedating effects

14. Dermal exposure to which of the following chemical weapons is most likely to produce seizures and increased body secretions?

A. Chlorine

B. Hydrogen cyanide

C. Lewisite

D. Sarin

15. The pharmacologic mechanism of action of a nerve agent is most similar to which of the following drug categories?

A. Anticholinergics

B. Anticholinesterases

C. Calcium channel blockers

D. Opioids

SELF-ASSESSMENT QUESTIONS-ANSWERS

1. **A.** Medicines were the most frequently involved (49%) substances for all age groups. While children account for most reported exposures to poison control centers, fatal poisonings are more common in adults. Intentional poisonings are most common in adults; however, approximately 23% of pediatric exposures reported to the National Poison Data System in 2020 were intentional. Both children and adults may not recognize a product's risk of toxicity.

2. **B.** In patients that are not at risk of aspiration, drinking 2 to 4 ounces (60 - 120 mL) of water promotes dilution which may reduce the absorption of the ingested poison or minimize the poison clinical effects related to gastric irritation. Following ocular chemical exposures, the open eye should be flooded with lukewarm or cool water poured from a glass 2 to 3 in. (5-8 cm) before flushing the eye. Afterwards, the eyes should be flushed for 10 to 15 continuous minutes. Poison Control Centers should be contacted as soon as possible regardless of symptom development. Inhaled poisonings have varying particle sizes and can be small enough to pass through a handkerchief leading to toxicity.

3. **B.** Activated charcoal is the most common method of gastric decontamination due to its effectiveness and safety profile when administered early following the ingestion of an oral agent in patients who are not at risk of aspiration. Gastric lavage and whole bowel irritation are only administered in certain poisonings in which activated charcoal cannot be used. Gastric lavage is not routinely recommended due to it being a more invasive procedure that only experienced clinicians should perform due to its complications. Whole bowel irrigation is used for specific ingestions, such as delayed-release or enteric coated drug formulations, iron, lithium, and potassium. Cathartics are rarely if ever given without concurrent activated

charcoal administration. Cathartics should only be given once and only if bowel sounds are present.

4. **C.** A 10-hour serum acetaminophen concentration of 100 µg/mL (660 µmol/L) crosses the Rumack-Matthew nomogram line indicating the need for treatment with acetylcysteine. Acetylcysteine is most effective when administered within 10 hours of the ingestion. Intravenous acetylcysteine would be preferred in this situation, because the unpalatable taste and high incidence of vomiting after oral acetylcysteine can lead to delays or interruptions in antidote therapy which puts the patient at an increased risk of developing hepatotoxicity. Activated charcoal would not be appropriate for this patient, since the ingestion occurred more than 2 hours ago and the patient is actively vomiting, which would put them at risk of aspirating the activated charcoal. Serum acetaminophen concentrations are reliable after 4 hours from the time of ingestion, so there is no need to repeat the drug level to determine if antidote therapy is indicated.
5. **B.** The standard acetylcysteine treatment course is 21 hours with the intravenous formulation and 72 hours with the oral formulation, respectively. Medication administration errors, including delays in treatment related preparation, administration of the "three-bag" acetylcysteine in the incorrect order, and administration of the "three-bag" acetylcysteine over the incorrect time frame, have been reported with the intravenous formulation of acetylcysteine. Oral acetylcysteine has a total dose of 1440 mg/kg which is greater than the total dose of 300 mg/kg with the intravenous formulation. Oral acetylcysteine is associated with more adverse effects related to nausea and vomiting while the intravenous acetylcysteine has been associated with more anaphylactoid reactions.
6. **A.** Atropine is the preferred antidote for a cholinergic toxidrome. Diphenhydramine would not reduce the excessive secretions and oral administration would be challenging in patients already having difficulty managing their secretions. Physostigmine is the antidote for symptomatic patients experiencing an anticholinergic toxidrome. Pralidoxime can be administered for organophosphate toxicity; however, it would be administered in conjunction with atropine and the intravenous administration of pralidoxime would be preferred over intramuscular administration.
7. **D.** Bronchorrhea and bronchospasms are often responsible for fatal organophosphate insecticide poisonings. Pralidoxime helps to treat the respiratory muscle weakness, and improved respirator rates and efforts are appropriate endpoints of therapy. The amount of atropine needed to treat organophosphate insecticide poisoning often exceeds the doses used to treat bradycardia in non-poisoned patients. Tachycardia is tolerated with atropine treatment in order to reverse the cholinergic toxidrome-related bradycardia, bronchorrhea, and bronchospasms. The intended effect of our treatments for organophosphate insecticide poisoning is to dry the excessive secretions to prevent the patient from drowning in their own secretions.
8. **C.** Calcium channel blockers, beta adrenergic blockers, and digoxin are all cardiac toxins. Coingestion of these agents can lead to additive or synergistic toxicity resulting in hypotension, bradycardia, and dysrhythmias. Nondihydropyridine calcium channel antagonists are more commonly reported in severe calcium channel blocker overdoses; however, both dihydropyridine and nondihydropyridine calcium channel antagonists result in similar toxicities. Calcium channel antagonist overdoses most often result in hyperglycemia while beta adrenergic blockers typically cause hypoglycemia. Toxicity presents within hours and is not delayed by 6 to 18 hours following overdoses of immediate release calcium channel antagonists.
9. **A.** Calcium chloride is usually given first for bradycardia related to a calcium channel blocker overdose, because it is readily available, can be administered quickly, and mechanistically helps to counteract the adverse effects of this type of overdose. Vasopressors like norepinephrine may be used to treat bradycardia and hypotension; however, they are typically given after or in addition to calcium. Many institutions require patients receiving continuous infusions of vasopressors to be admitted to the intensive care unit, which may prompt providers to see if patients can be successfully managed with intravenous calcium and supportive care first. Additionally, central access is preferred for vasopressor administration while intravenous calcium gluconate can be given safely through peripheral intravenous lines. Atropine may be used for bradycardia; however, it often does not reverse bradycardia from calcium channel antagonist overdoses because it does not target the mechanisms in which this type of overdose causes the bradycardia and hypotension. Lipid intravenous emulsion therapy would only be considered in cases refractory to standard of care treatment with calcium, vasopressors, or high-dose insulin therapy.
10. **C.** The anticholinergic toxidrome mnemonic consists of "hot as a hare" (fever), "red as a beet" (flushed skin), "blind as a bat" (mydriasis), "dry as a bone" (dry mouth, decreased sweating), "mad as a hatter" (delirium), and "full as a flask" (urinary retention). Tachycardia is also seen with anticholinergic toxicity. The opioid toxidrome consists of coma, respiratory depression, and miosis. Beta adrenergic blocker toxicity can result in hypotension, bradycardia, altered mental status, and hypoglycemia. Cholinergic toxicity results in diarrhea, urination, miosis, bronchospasm,

bronchorrhea, bradycardia, emesis, lethargy, lacrimation, and salivation (“DUMBELLS” menumonic).

11. **D.** Physostigmine is the preferred antidote for moderate-to-severe anticholinergic toxicity without evidence of QRS prolongation on ECG. Patients treated with physostigmine have shorter recovery times and fewer complications compared to patients treated with benzodiazepines. Pralidoxime and atropine are treatments for cholinergic toxicity. Lorazepam may be used for anticholinergic toxicity; however, physostigmine is more effective than benzodiazepines at controlling agitation and reversing delirium associated with anticholinergic toxicity.

12. **A.** The opioid toxidrome consists of the triad of respiratory depression, coma, and miosis. Calcium channel blocker toxicity can result in hypotension, bradycardia, and hyperglycemia. Muscle fasciculations would be uncommon with opioid overdoses. Muscle fasciculations, miosis, and difficulty breathing can be observed along with other symptoms in patients experiencing cholinergic toxicity from organophosate insecticide poisonings or nerve gases. Vomiting, diarrhea, and hypotension are not common signs of an acute opioid overdose. Vomiting and diarrhea would be more characteristic of acute opioid withdrawal.

13. **D.** Naloxone will reverse respiratory and central nervous system depression related to opioid toxicity; however, it will not reverse the sedating properties of other medications or toxins with sedative hypnotic effects. Naloxone for opioid reversal is not administered orally so gastrointestinal motility does not factor in. Hyperglycemia does not impact naloxone’s ability to reverse opioids. Naloxone is still effective for patients with opioid dependence. Acute opioid withdrawal can be seen following naloxone administration in patients with a history of opioid dependence.

14. **D.** Sarin, a nerve agent, can cause seizures and increased secretions. Chlorine, hydrogen cyanide, and lewisite are other chemical weapons. Chlorine gas is a pulmonary irritant. Hydrogen cyanide is a “knock out” gas and exposures can lead to seizure, coma, hypotension, lactic acidosis, and cardiac arrest. Lewisite exposures cause painful blisters on the skin, shortness of breath, cough, gastrointestinal distress, and hypotension.

15. **B.** Nerve agents are well characterized by its anticholinesterase action and resultant cholinergic toxicity. Anticholinergics are competitive antagonists of acetylcholine at the muscarinic receptors and lead to a toxidrome that is almost the opposite of the cholinergic toxidrome seen with nerve agents. Calcium channel blockers inhibit. Opioids are agonists of the μ, κ, and δ receptors.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e >

Chapter e9: Fever

Jamal Brown; Juan Mosley, II

KEY CONCEPTS

KEY CONCEPTS

① Fever can be a by-product of various infectious or pathologic processes, vaccinations, medications, and environmental exposure, or of vigorous activity.

② Normal body temperature fluctuates and is regulated in the thermoregulatory center of the anterior hypothalamus. During a fever, prostaglandins cause an increase in the hypothalamic temperature set point and thereby increase production of heat in the periphery.

③ Healthcare professionals should COLLECT key information on medications, medical history, immunizations, recent travel, social history, barriers of care, and course of fever.

④ Using the gathered data, ASSESS information to differentiate symptoms from surrounding conditions, determine appropriateness for self-care, evaluate history for causes of fever, and consider the most appropriate medication for fever.

⑤ Goals of therapy include relieving discomfort, reducing body temperature, and when appropriate treating the underlying cause of fever.

⑥ Nondrug treatments include the use of cooling blankets, which should only be used along with antipyretics. Appropriate hydration and the use of fans also contribute to decreasing body temperature.

⑦ Nonsteroidal anti-inflammatory drugs (NSAIDs) reduce fever, but they can adversely affect the gastrointestinal tract and platelets. For this reason, acetaminophen is the preferred agent to reduce fever in most patients. Therapy with NSAIDs and acetaminophen combinations can be used in most but not all patients.

⑧ Medical evaluation should be sought if symptoms of fever do not resolve with over-the-counter treatment within 24 hours in children younger than 2 years, 48 hours in other children and 3 days in adults. Also, a medical evaluation should occur in patients with alarming symptoms regardless of their temperature.

PATIENT CARE PROCESS

Patient Care Process for Fever

Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient demographics (eg, sex, age, pregnancy)
- Active medical problem list
- Medication history/list (prescription and over the counter) and adherence
- Inquire about immunizations
- Inquire about history of allergies and adverse effects
- Inquire about recent travel, climate, and social activities
- Gather log of temperatures and duration of current symptoms
- Collect information pertaining to the patient's medication experience (eg, beliefs, expectations, and cultural considerations related to medications)
- Inquire about the patient's ability to access medications, considering ability to pick up medications and ability to afford medications
- Inquire as to how the process of managing medications works at home (eg, pill boxes, calendars, reminders)

Assess

- Decipher appropriateness of self-care for the patient
- Complete differential diagnosis between fever, hyperthermia, and hyperpyrexia
- Evaluate activities and social factors that may predispose the patient to fever
- Assess recent travel and potential environmental causes of fever
- Analyze the patient's active and prior medical conditions for associations with fever

- Assess the indication, safety, adherence, and effectiveness of each medication the patient is taking
- Understand patient's willingness to take over-the-counter (OTC) therapy for fever and if religious/cultural barriers to therapy exist
- Consider interactions between current OTC, prescription, and herbal medications when assessing therapy options for fever

Plan

- Develop a care plan to reduce fever and underlying cause
- Identify the monitoring parameters such as temperature and discomfort to assess ongoing effectiveness, safety, and adherence, including frequency of follow-up monitoring
- Design personalized education on checking temperature consistently and nonpharmacological approaches to reduce temperature
- Review and reconcile all medication lists to arrive at an accurate and updated medication list
- Determine who will implement components of the care plan
- Determine the appropriate timeframe for patient follow-up
- Determine the appropriate mode for follow-up or referral

Implement*

- Discuss the care plan with the patient and direct selection of appropriate over-the-counter therapy
- Educate the patient on the most appropriate antipyretic medication and goals of therapy, adverse effects, interactions, and precautions
- Ensure patient understanding and agreement with the plan
- Communicate instructions for follow-up and discuss must appropriate follow-up if needed

Follow-up

- If therapy is not effective in 3 days in adults, within 48 hours in children age 2 years or older, or within 24 hours in children younger than 2 years, advise the patient or caregiver to seek medical care. Depending on the presence of alarming symptoms, urgent/emergent care may be needed.

**Collaborate with patients, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

In a small group, create a drug treatment table of OTC products for fever. Consider appropriate age, mechanism of action, dosing schedule, disease interactions, drug interactions, and cost. Compare and contrast these agents based on these factors and create an "optimal" situation to use each medication. Also, create a list of conditions that mimic symptoms of fever. This will assist you during the Assess phase of the Patient Care Process.

INTRODUCTION

Healthcare professionals are often the first point of contact for patients who present with nonspecific symptoms that can be transient and self-limiting or that indicate the presence of serious disease. Collecting the information needed to assess these symptoms and make a recommendation to patients is a common and important activity of health professionals as they provide direct patient care.

① Elevated body temperature is one of these cardinal manifestations of disease. Fever and elevated temperatures can be associated with many etiologies related to recent travel, illnesses, activity, and environmental factors. Healthcare professionals have an opportunity and responsibility to decipher information to help patients find an appropriate treatment to decrease temperatures and alleviate associated symptoms or to seek more extensive medical evaluations.

A systematic process for assessing elevated temperatures includes asking the patient or caregiver for specific facts about the condition, examining the patient and measuring the body temperature, assessing the collected information, developing and implementing a treatment plan (including referring the patient when red flags to self-treatment are present), and scheduling appropriate follow-up. This chapter reviews the causes of fever in a clinic or pharmacy setting and appropriate evidence-based treatment to alleviate symptoms.

EPIDEMIOLOGY AND ETIOLOGY

Fever and elevated temperatures are common reasons for visits to ambulatory care settings. According to the National Ambulatory Medical Care Survey, fever is the third leading cause of emergency department visits in all patients and the leading cause of these visits in patients younger than 15 years old.[2,3] In emergency department settings, 5.5 million patients are treated annually for fever in the United States.

IFever and upper respiratory infections were the most common reasons for return visits to urgent care and emergency departments in a pediatric study.[4] Fever is regarded as one of the most common reasons for office visits, emergency department encounters, and after-hours telephone calls.[5]

ANATOMY AND MECHANISM OF DISEASE

② Body temperature is regulated by the thermoregulatory center in the anterior hypothalamus and fluctuates throughout the day.[6] The circadian rhythm controls the internal thermostat, which is set between the morning low temperature and the afternoon peak temperature. When a patient has a fever, the hypothalamus has been “reset” to a higher temperature.

Fever is defined as a controlled elevation of body temperature above normal range, which is from 36.7°C to 37°C (98°F–98.6°F) orally. Rectal temperatures are 0.6°C (1°F) higher and axillary temperatures are 0.6°C (1°F) lower than oral temperatures.

Fevers can originate from infections, malignancies, autoimmune disorders, and other causes.[7] As causes of fever, inflammatory diseases and fever of unknown origin (often in complex patients with many potential causes) have increased over time, while infections and malignancies have decreased.[1] Many common infections can cause fever such as osteomyelitis, appendicitis, meningitis, and disorders of the skin, respiratory tract, urinary tract, sinuses, and ears.[8,9] Common malignancies with a manifestation of fever include lymphoma, leukemia, renal cell carcinoma, and hepatocellular carcinoma.[10]

Various medications can also be the cause of fever and must be evaluated in patients presenting with symptoms (Table e9-1). A drug-induced fever is a persistent fever without an infection or another underlying condition. Drug regimens must be evaluated in patients presenting with signs and symptoms of fever to rule out potential causative agents. In this type of fever, symptoms coincide with the administration of the offending agent and subside on its withdrawal, after which the temperature remains normal. Numerous medications can produce fever, but β-lactam antibiotics, anticonvulsants, allopurinol, hydralazine, nitrofurantoin, sulfonamides, phenothiazines, and methyldopa are most often implicated.

TABLE e9-1

Medications that Can Cause Fever

- **Anticonvulsants**
- Barbiturates
- Carbamazepine (eg, Tegretol)
- Phenytoin (eg, Dilantin)
- **Antimicrobials**
- Carbapenems
- Cephalosporins
- Erythromycin
- Isoniazid
- Minocycline (eg, Minocin)
- Nitrofurantoin (eg, Furadantin)
- Penicillins
- Rifampin
- Sulfonamides
- **Cardiovascular drugs**
- Captopril (eg, Capoten)
- Hydralazine
- Hydrochlorothiazide
- Methyldopa
- Nifedipine (eg, Procardia)
- Procainamide
- Quinidine
- **Histamine H_2 antagonists**
- Cimetidine (eg, Tagamet)
- Ranitidine (eg, Zantac)
- **Nonsteroidal anti-inflammatory drugs**
- Ibuprofen
- Salicylates
- Sulindac (eg, Clinoril)
- **Others**
- Allopurinol (eg, Zyloprim)
- Heparin
- Meperidine (eg, Demerol)
- Phenothiazines

Data from References 11–14.

COLLECT

③ When patients present to a community or other ambulatory settings with symptoms of fever, the first step in the patient care is collecting information from the patient, medical chart, history, or family members. The complaint of fever should be based on a reading from a thermometer as compared to feeling a part of the forehead or other body part for an increase in warmth. During the course of the fever, patients should use the same thermometer and site of measurement, as temperatures can vary with different instruments and sites of measurement (Table e9-2).

TABLE e9-2

Normal Temperature Ranges when Measured at Different Body Sites

Body Sites (Type of Measurement)	Normal Ranges	Fever Point
Axillary (mercury in glass; electronic)	34.7°C-37.4°C (94.5°F-99.3°F)	37.4°C (99.4°F)
Sublingual (mercury in glass; electronic)	35.5°C-37.6°C (95.9°F-99.6°F)	37.6°C (99.6°F)
Rectal (mercury in glass; electronic)	36.6°C-37.9°C (97.9°F-100.2°F)	38°C (100.4°F)
Tympanic (infrared)	35.7°C-37.6°C (96.3°F-99.6°F)	37.6°C (99.6°F)
Temporal (infrared)	36.6°C (97.9°F) to temperature specific for patient age shown in next column	• 38.1°C (100.6°F) for (0-2 months old) • 37.9°C (100.2°F) for (3-47 months old) • 37.8°C (100.0°F) for (>4 years old)

Data from References 21,38.

Once a fever has been properly verified, the underlying cause should be determined. Relevant information includes the chronology of fever, existing conditions, current medications, vaccination history, exposure to infected individuals, and recent travel. Patients with conditions such as coronavirus disease 2019 (COVID-19) may have symptoms that appear as soon as 2 days after exposure.[15] Moderate-to-severe illness with or without fever can occur with vaccinations.[16] For recent travelers, a thorough geographical history, time of onset, and duration of fever symptoms is important.[17] Patients returning from tropical areas with infections usually become symptomatic within 21 days of exposure to pathogens, and the majority of returning travelers who develop fever present within 1 month of exposure.[15,18] Fever is more commonly associated with travel to sub-Saharan Africa, South and Central Asia, Southeast Asia, Latin America, and the Caribbean.[17]

Special Populations

Several types of patients with fever have red flags indicating that self-care is not appropriate. Fever, hyperthermia, and hyperpyrexia are similar conditions where patients will exhibit elevated temperatures. It is important to distinguish between fever and hyperthermia, as hyperthermia does not respond to antipyretics and can be rapidly fatal. Hyperthermia—an uncontrolled rise in body temperature—results from the body taking on or producing heat faster than peripheral mechanisms can lose it; the hypothalamic set point is not altered, and the elevated temperature will not respond to antipyretic agents. Hyperthermia can result from exposure to extremely high temperatures (such as in a closed car or other vehicles) or engaging in heavy labor or strenuous exercise.[19] To appropriately distinguish this condition from fever, a careful examination of recent events with exposure to elevated temperatures or layering of clothing should be examined.[19] Patterns of fluid intake should also be evaluated, as some patients with hyperthermia suffer from dehydration. In addition, providers should rule out medications that may have caused excess temperatures. If patients report taking antipyretics with no decrease in temperatures, this may also assist in differentiating hyperthermia from fever.

A fever of greater than 41.5°C (106.7°F) is defined as hyperpyrexia, which can be distinguished from fever and hyperthermia by the extreme elevation in temperature. An additional discriminating factor is that hyperpyrexia responds to antipyretics, unlike hyperthermia. Hyperpyrexia can result from bacterial or viral infections, and it occurs when the hypothalamic set point is increased, resulting in heat-producing responses in the periphery (such as shivering). While hyperpyrexia will respond to antipyretic agents (unlike hyperthermia), the extremely high body temperature is a red-flag medical emergency that requires immediate attention.[19] Those at risk for hyperthermia who have severe symptoms of infection that are not self-limiting, or who have impaired oxygen utilization, should see a medical professional immediately.[20] Also, patients who have an impaired immune function, or damage to the central nervous system (CNS) should see the physician immediately.

Children represent one of the largest groups of patients who may need evaluation by a physician immediately to avoid worsening of symptoms or further harm. Table e9-3 includes circumstances when children, adolescents, and adults presenting with fever should seek medical care.

TABLE e9-3

Red-Flag Symptoms in Patients with Fever

Patients presenting with a temperature greater than 38°C (100.4°F) and any of following symptoms should see a physician immediately[a]:

- Unexplained dermatologic spots or rashes[b,c,d]
- Loss of appetite, low energy, or is noticeably pale or flushed[b,c,d]
- Inability to swallow and drooling excessively[b,c]
- Difficulty breathing even after clearing nose with a bulb syringe[b,c]
- Refusing oral fluids[b]
- Very ill, drowsy or difficult to wake up[b,c]
- Delirious, glassy-eyed, or extremely cranky or irritable[b,c]
- Environmental exposure to high temperatures[b,c,d]
- Vomiting without the ability to keep down fluids and/or sustained diarrhea[b,c]
- History of seizures or febrile seizures[b,c,d]
- Stiff neck, severe headache, severe ear pain, or sore throat[b,c,d]
- Taking steroids or are immunocompromised with conditions such as cancer or sickle cell conditions[b,c,d]
- Changes in mental status[b,c,d]
- Dizzy or light-headed[d]
- Recent chemotherapy[d]
- Shortness of breath/chest pain[d]
- Changes in the color of skin, lips, or nail beds[b,c,d]

[a] Infants younger than 3 months with a temperature above 38°C (100.4°F), children of any age with a temperature above 40°C (104°F), or adults with high fever (above 41°C [105.8°F]) should be seen by the physician irrespective of accompanying symptoms.

[b] Applies to children.

[c] Applies to adolescents.

[d] Applies to adults.

Data from References 22-24.

ASSESS

④ After the information has been collected from the patient, the next step of the process is to make an assessment to draw conclusions of the condition and its origin. Assessing the patient should include differentiating fever from other conditions that produce elevated body temperatures, including hyperthermia and hyperpyrexia. The pharmacist or other primary care practitioner must ensure that the symptoms are limited to a fever before treatment is given.

The gathered information must be examined in detail to ascertain whether recent travel, drugs, illnesses, or other identifiable factors have led to fever. For medications, this includes an assessment of indication, effectiveness, safety, and adherence. A problem list of active medical problems and medication therapy problems is then created to prioritize medication therapy recommendations and achieve goals of therapy.

After evaluating the possibility of these and other potential red-flag symptoms, the health professional must decide whether to recommend use of self-care agents for fever. If patients have red flag symptoms such as those shown in Table e9-3, the pharmacist should assist the patient in seeking immediate medical care. Religious and cultural preferences should be considered so that patients are able to make a joint decision that aligns with their values. Economic barriers must be assessed as they may alter decisions of care based on cost. Guiding patients to generic equivalents may allow them to be more adherent to regimens because of the affordability of the needed treatment.

Concurrent prescription medications, dietary supplements, and OTC therapies should also be considered. Drug interactions can affect therapy options. If available, a comprehensive medical chart may also provide information on key laboratory values including complete blood count, kidney function, liver function, and basic metabolic panel. When laboratory data are not available, the medical history can provide insight on whether conditions such as liver dysfunction or renal dysfunction are present.

DEVELOP A CARE PLAN

⑤ Upon completion of the assessment of the patient with fever, an individualized patient-centered care plan that is evidence-based and as affordable as possible is created for the patient. This plan includes recommendations of nonpharmacologic and pharmacologic strategies to reduce fever and prevent further complications.

⑥ Nonpharmacologic methods of managing fever include the patient wearing light clothing, keeping a low room temperature to stay comfortable, and taking a sponge bath with warm water.[24] Patients should not receive alcohol or ice baths due to the potential for shock. If patients begin shivering when sponging with tepid water, that intervention should be terminated.[24] Because sponging does not reduce the hypothalamic set point, sponging should follow oral antipyretic therapy by 1 hour to permit the appropriate reduction of the hypothalamic set point and a more sustained temperature-lowering response.[20] Since fever will cause a more rapid loss of fluids, patients should make sure to increase fluid intake to avoid dehydration.

⑦ All antipyretics are dosed on an as-needed basis for fever. When considering pharmacologic therapy, over-the-counter antipyretics include acetaminophen, ibuprofen, and aspirin. Acetaminophen reduces fever by inhibiting the production and release of prostaglandins in the CNS and by inhibiting endogenous pyrogens at the hypothalamic thermoregulatory center.[25]

In adults, acetaminophen is dosed at 650 mg every 4 to 6 hours (maximum dose of 3,250 mg/24 hr) or 1,000 mg every 6 hours (maximum dose of 3000 mg/24 hr). Patients with liver disease should consult a medical professional before using acetaminophen. In the United States, product labeling warns against use of more than 4,000 mg/day, with other drug products containing acetaminophen (eg, combination products such as those containing opioids plus acetaminophen, or in those who consume three or more alcoholic drinks every day during use of the product).[25] Because this medication is marketed in 325 mg, 500 mg, and 650 mg tablets, the pharmacist should help the patient to identify the proper dosage and dosing schedule to avoid confusion.

In children, the dose is 10 to 15 mg/kg every 4 to 6 hours as needed with a maximum of 75 mg/kg/day for infants and lesser of 100 mg/kg/day or 1,625 mg/day in children.[25] Dosing amounts are provided by weight and age on product labeling; weight should be used rather than age to guide dosing amounts whenever possible.[25]

Oral acetaminophen is safe to use in pregnancy and lactation and is classified as Food and Drug Administration pregnancy category B.[25] As dose adjustments are required for renal impairment, patients should consult their physician if renal complications exist. This medication is contraindicated in active and severe hepatic impairment. Patients with a history of alcohol abuse should use acetaminophen with caution.

Ibuprofen reduces fever by inhibiting the production and release of prostaglandins in the CNS and periphery. Ibuprofen is dosed at 200 to 400 mg orally every 4 to 6 hours with a maximum of 1,200 mg/day in children greater than 12 years old and in adults.[26] In children 6 months to 12 years of age, the dose is 5 to 10 mg/kg orally every 6 to 8 hours as needed, with a maximum of 4 doses/day.[27] Patients younger than 2 years of age should use the 50 mg/1.25 mL suspension and children 2 years or older should use the 100 mg/5 mL formulation. Parents with children in mixed-age ranges should be advised to pay close attention to formulations to avoid overdose.

Patients with a history of renal complications should only take ibuprofen with the approval of their physician, as dose adjustments may be required. Ibuprofen should be avoided in older adults with heart failure because of possible fluid retention and heart failure exacerbation. Ibuprofen should also be avoided in older adults with stage 4 or 5 chronic kidney disease stage as renal injury may occur.[28] Patients with cardiovascular disease should discuss treatment with a physician, as nonsteroidal anti-inflammatory drugs (NSAIDs) may increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke.[29] Also, ibuprofen cannot be used in patients undergoing coronary artery bypass graft surgery and can cause serious gastrointestinal adverse events, including bleeding, ulceration, and perforation of the stomach or intestines.[29] This medication should not be used in pregnancy or during breastfeeding, as risks to the fetus or infant cannot be ruled out.[30]

Similar to ibuprofen, aspirin reduces fever by inhibiting the production and release of prostaglandins in the CNS and periphery. In children aged 12 years or older and adults, aspirin is taken at the dose of 325 to 650 mg orally every 4 to 6 hours as needed with a maximum of 4 g in 24 hours. Children and teenagers who have or are recovering from chickenpox or flu-like symptoms should not use aspirin, as Reye's syndrome may occur.[31] Patients with renal or hepatic disease should discuss the use of this medication with a physician; use in severe hepatic and renal impairment is contraindicated. At doses used for treatment of fever, aspirin should be avoided in pregnancy and lactation.[31]

IMPLEMENT

After the therapy options have been identified, the step of implementation includes starting the treatment plan along with the patient and in consultation with other healthcare practitioners when appropriate. Based on patient-specific parameters, therapy options are discussed with the patient and education is provided on the goal of reducing temperature and discomfort associated with fever. The patient should be advised to check body temperatures using the same instrument in a specific-body location and to take antipyretic agents on the recommended schedule. Contraindications, cautions, adverse effects, and pertinent interactions of the selected medication should be discussed with the patient and/or caregivers.

An open-ended dialogue should occur to verify that the patient is comfortable with the medication choice, affordability of the agent, and schedule/duration of therapy.

FOLLOW-UP

⑧ Monitoring and evaluation of fever treatment is focused on symptom management. Worsening or improvement of symptoms aids in the evaluation of the treatment that is administered. Patients should be instructed to keep a fever diary with recorded temperatures every 8 hours and symptoms they experience.[32] A fever diary can assist in evaluation if further treatment becomes necessary by the healthcare team. If fever or associated symptoms have not changed within 3 days of the start of antipyretic therapy, the patient should seek further evaluation.[20]

During treatment for fever, development of other symptoms is concerning. Headache or neck stiffness may be indicative of meningitis; a lumbar puncture may be needed for diagnosis.[6,33] Fever presenting with diarrhea and abdominal pain can indicate a bacterial infection that requires evaluation using laboratory tests.[32] Documented recent travel history and new symptom presentation further increase the possible causes of fever. For example, prolonged fever with symptoms such as rash, myalgias, gastrointestinal upset, or headaches can indicate dengue fever in those with recent travel history to tropical and subtropical climates.[34]

The symptoms of fever, cough, or shortness of breath were reported by 70% of patients with COVID-19. Common signs and symptoms of COVID-19 tend to overlap with other infections and fever causing ailments. Differentiation by further evaluation and testing is needed to adequately identify and treat the underlying cause.[35] Although some patients infected with COVID-19 are asymptomatic, recommending antipyretic therapy in those of need should be indistinguishable from the red-flag symptoms, recommendations, and treatments previously outlined.[35] If COVID-19 infection or exposure is suspected, patients should be advised to follow guidance protocols set forth by the Centers for Disease Control and Prevention.

In patients with hyperthermia, antipyretic therapy is not effective. In addition to fever, the patient may experience confusion, hypotension, dehydration, dry and hot skin, and delirium.[6,36,37] Cooling techniques such as cool blankets, fans, and sponging can be used in patients with hyperthermia, but further and immediate evaluation is needed to determine and treat the true underlying cause.[37]

Fever in children may present with other symptoms such as loss of appetite, sleep, and decreased activity.[36] When these symptoms occur, alleviating other symptoms of discomfort is vital.[36] If the child's condition worsens or there is no improvement within 24 hours for children younger than 2 years or 48 hours for children older than 2 years, the child should be further evaluated by a physician.[21]

CONCLUSION

Patients in the community and ambulatory settings frequently seek care for fever. These practitioners have the opportunity to implement the patient care process in a systematic way to understand the causes of fever and assist patients in meeting therapy goals. Assessments can be made as to whether present medication regimens may be optimal and if patients have red-flag symptoms that make self-care inadvisable.

Patient-specific factors, values, beliefs, and comfort are considered in developing, implementing, and following-up on a treatment plan. At-home measures are used to assist with decreasing temperature safely, and in those self-treating fever, counseling should be provided on how to most effectively and safely use antipyretics to resolve symptoms. Patients whose fever does not resolve and those who develop other symptoms that are indicators of red-flag conditions should be referred for immediate medical evaluation.

This patient-centered care model ensures that the symptoms of fever are adequately resolved and that the encounters patients have with healthcare professionals are trustworthy, meaningful, and comprehensive.

SELF-ASSESSMENT QUESTIONS

1. Which of the following medications is generally preferred in treating fever?

A. Ibuprofen

B. Naproxen

C. Aspirin

D. Acetaminophen

E. Magnesium Salicylate

2. Which of the following nonpharmacologic methods of reducing fever is preferred?

A. Use of an alcohol bath

B. Using cooling fans

C. Wearing tight clothing

D. Using a cold water sponge bath

E. Using an ice bath

3. Cindy is a 27-year-old woman who has had an elevated temperature for the last 2 days. She reports having a slightly elevated temperature and calls your pharmacy for dosing advice. At home, she has acetaminophen 500-mg tablets to treat her fever. What is the daily maximum recommended dose of this medication for her to use?

A. 2,000 mg

B. 2,400 mg

C. 3,000 mg

D. 3,250 mg

E. 4,000 mg

4. How long should adults use over-the-counter treatment with no changes in temperature before seeking care of the physician?

A. 2 days

B. 3 days

C. 5 days

D. 7 days

E. 10 days

5. Matthew is an 11-month-old child who is being brought to your pharmacy by his father. He has no history of medical conditions and weighs 10 kg. The father reports that Matthew's temperature at home has been 101°F (38.3°C) and has developed a slight rash behind his left ear. He does not appear to be irritable and has been properly hydrating at home. Which of the following is your recommendation for Matthew?

A. Take a bath in tepid water.

B. Take Ibuprofen 100 mg q 4 hours.

C. Dress Matthew in loose clothing.

D. Take Naproxen 110 mg q 4 hours.

E. See the pediatrician.

6. If symptoms do not improve or worsen with over-the-counter therapy in children less than 2 years old, when should the pediatrician be seen?

A. 12 hours

B. 24 hours

C. 36 hours

D. 48 hours

E. 72 hours

7. Which of the following medications is likely to produce symptoms of the fever?

A. Bactrim

B. Lisinopril

C. Lovenox

D. Doxycycline

E. Hydroxychloroquine

8. On a Tuesday morning, a 37-year-old man presents to your pharmacy with a 2-day history of fever symptoms. Ted has been taking ibuprofen 400 mg every 6 hours over the last 2 days but has noticed that his fever has not decreased. He reports that he competed in a track meet over the weekend where the temperatures were above 95°F (35°C). Upon checking his temperature this morning, his last reading was 102.3°F (39.1°C). What do you recommend?

A. Switch to acetaminophen 1,000 mg every 6 hours.

B. Switch to aspirin 650 mg every 4 hours.

C. Continue therapy for another 24 hours.

D. See a physician immediately for possible hyperpyrexia.

E. See a physician immediately for possible hyperthermia.

9. Christina is a 24-year-old pregnant woman who presents to your pharmacy. She explains to you that she is in her 2nd trimester of pregnancy. She has had a fever for the last 24 hours and has a temperature of 103°F (39.4°C). She has no history of renal or hepatic complications. Which of the following medications is the most appropriate for her to use?

A. Ibuprofen

B. Acetaminophen

C. Naproxen

D. Aspirin

E. Magnesium Salicylate

10. Children of any age should be referred to the physician if they have a temperature that exceeds what temperature?

A. 101°F (38.3°C)

B. 102°F (38.9°C)

C. 103°F (39.4°C)

D. 104°F (40°C)

E. 105°F (40.6°C)

11. Children with a temperature exceeding 100.4°F (38°C)and the following symptoms should see the physician immediately EXCEPT:

A. Children who refuse intake of fluids

B. Children who appear irritable or very ill

C. Children with a history of asthma

D. Children that report with a stiff neck

E. Children who have been in a very hot place like a car

12. As sponging does not reduce the hypothalamic set point, it should be used after what time period has elapsed after administration of oral antipyretic therapy?

A. 1 hour

B. 2 hours

C. 3 hours

D. 4 hours

13. Jennifer brings her 13-year-old daughter, Suzie, to the pharmacy with a temperature of 101°F (38.3°C). Jennifer only has aspirin at home but is on a limited income and would prefer not to spend her money on additional drugs if possible. What is your recommendation for treatment of Suzie?

A. Yes, aspirin can be taken without complication.

B. Yes, aspirin can be taken, but with the physician's approval.

C. No, aspirin cannot be taken due to Reye's syndrome risk.

D. No, aspirin cannot be taken because it is not indicated for fever.

E. No, aspirin cannot be taken because exclusions for self-care are present.

14. Which of the following categories requires a referral to the physician?

A. Infants younger than 3 months with a temperature above 98.6°F (37°C)

B. Children with a temperature above 100.4°F (38°C) refusing oral fluids

C. Children of any age with a temperature above 100.4°F (38°C)

D. Children with a temperature above 100.4°F (38°C) who appear hungry

E. Adults with a temperature above 104°F (40°C)

15. Which of the following are proper at-home measures to take when treating fever?

A. Using the same thermometer during the course of fever

B. Using cool water baths to bring down the temperature

C. Using the hand to check the temperature on the forehead

D. Using versatile measurement sites to ensure accuracy

E. Using alcohol baths to cool the skin

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** Acetaminophen is generally the drug of choice for fever, as it does not cause unwanted side effects on platelets and the gastrointestinal tract such as Aspirin and NSAIDs. See section "Develop a Care Plan" for more details.

2. **B.** The usage of alcohol baths is dangerous and can induce shivering. Ice baths are also dangerous and can lead a patient to shock. Patients should use tepid water instead. Clothing should be light and loose. See the nonpharmacological recommendations under section "Develop a Care Plan."

3. **C.** The maximum dosage of Tylenol to be used for adults if taking the 500-mg tablets is 3,000 mg. If taking the 650-mg tablets, 3,250 mg is the daily maximum. See more dosage maximum information under section "Develop a Care Plan."

4. **B.** Adults should use self-care in 3 days if symptoms have not improved with the fever. Seeing the physician at this point allows for a more in-depth assessment of an underlying cause that is not improving. See section "Follow-Up" for more details.

5. **E.** Matthew has developed a small rash behind his ear. Children with temperatures exceeding 100.4°F (38°C) and who have developed a rash should see the pediatrician.

6. **B.** If symptoms do not improve or get worse with over-the-counter therapy in children less than 2 years old, a pediatrician should be seen in 24 hours. In children who are greater than 2 years old, this is extended to 48 hours. See section "Follow-Up" for more details.

7. **D.** Bactrim contains a sulfonamide drug, which can cause fever. Please see Table e9-1 for a more comprehensive list of medications.

8. **E.** Ted has hyperthermia and should seek medical care immediately. He was at a very hot event outside and has a temperature that has not decreased with the proper use of ibuprofen. His temperature has not exceeded 106.7°F (41.5°C), so we know that he does not have hyperpyrexia. See section "Assess" for more details.

9. **B.** The most appropriate drug to be used in pregnancy is acetaminophen. NSAIDs can cause adverse effects if used in pregnancy. See section "Develop a Care Plan" for more details.

10. **D.** Children of any age should be referred to the physician if they have a temperature that exceeds 104°F (40°C). Children with temperatures this high do not need to have accompanying symptoms to see the physician. See Table e9-3 for more details.

11. **C.** Asthma is not a part of the conditions that cause a child to seek treatment from a pediatrician with elevated temperatures. Although "impaired oxygen utilization" is mentioned in the chapter, patients are able to have a well-controlled asthma without this severe status. See Table e9-3 and section "Assess" for more details.

12. **A.** Sponging should occur 1 hour after the use of antipyretics to adequately decrease temperature. Sponging outside of the use of antipyretics is inappropriate, as this method does not decrease the hypothalamic set point. See section "Develop a Care Plan" for more details.

13. **A.** Children greater than 12 years old can safely take aspirin. Reye's syndrome becomes an issue in patients that are recovering from flu-like symptoms and the chickenpox. See section "Develop a Care Plan" for more details.

14. **B.** Hunger is not a part of the classic symptoms that patients experience in fever. The appropriate temperatures for medical referral (without considering symptoms) are greater than 100.4°F (38°C) in infants, greater than 104°F (40°C) in children, and greater than 105.8°F (41°C) in adults. See Table e9-3 for more details.

15. **A.** Water baths should be with tepid water, instead of cold water or alcohol baths that can induce shivering. While checking the temperature with a hand to the forehead may be a classic method of assessing fever, the recommended method is to use an appropriate thermometer. In addition, sites and measuring devices should remain the same during the course of therapy. See section "Develop a Care Plan" for more details.

Chapter e10: Pain and Headache

Ryan C. Costantino; Krista B. Highland; Laura Tilley

KEY CONCEPTS

KEY CONCEPTS

① A comprehensive pain symptom analysis should be performed on each individual reporting pain to determine the type of pain condition.

② A patient's self-report of pain impact, across a variety of biopsychosocial domains, is important to tailor and monitor treatment.

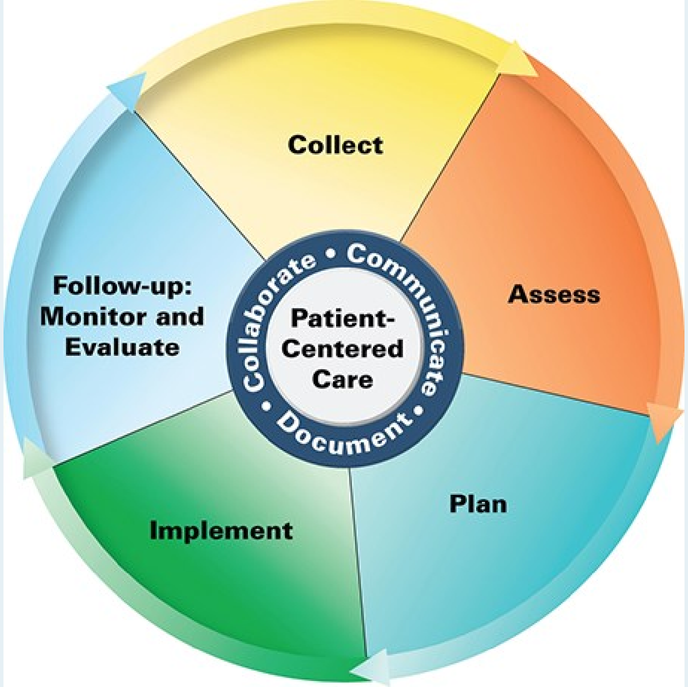
③ Appropriateness of self-care options to treat pain must be determined after careful review of red flag indicators.

④ The topical route of administration is preferred to oral analgesics whenever feasible.

⑤ Goals focused on quality of life and function in addition to traditional pain scores are preferred.

PATIENT CARE PROCESS

Patient Care Process for Pain Self-Care



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Pain Symptom Analysis (ie, PQRSTU, see Table e10-3)
- Patient characteristics (eg, age, allergies, pregnancy status)
- Medical history including cardiopulmonary, renal or hepatic disease, psychiatric and sleep disorders
- Social history (eg, tobacco/ethanol/illicit drug use), dietary habits, occupation
- Current medications including over-the-counter (OTC) aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), acetaminophen, herbal products, and dietary supplements
- Objective data
    - Physical examination: Temperature, blood pressure (BP), heart rate (HR), respiratory rate (RR), oxygen saturation, height, weight, diaphoresis, pallor, and visual inspection of the area of pain if possible (Note: Changes in vital signs are NOT diagnostic for pain and may not be present in patients with chronic pain. Changes may also be due to pathology other than pain (eg, tachycardia due to hemorrhagic shock).
    - There are no labs specific for pain assessment. Lab result abnormalities should be evaluated in light of a patient's chronic conditions (ie, elevated uric acid as an indicator of gout) or in evaluation of other suspected pathology.
- Pain can be categorized based on patient description and medical history

Assess

- Presence of risk factors that require medical referral (See Table e10-2)
- Classifications of pain
    - Nociceptive (visceral vs somatic)
    - Neuropathic (peripheral vs central)
- Duration of pain (acute vs chronic)
- Accessibility, ability, and motivation to adopt lifestyle modifications (eg, sleep hygiene, exercise) and mind-body techniques (eg, biofeedback, relaxation) as part of a comprehensive approach to pain
- Access to treatment options including medications, physical therapy, transcutaneous electrical nerve stimulation, and injectable epidurals
- Coexisting psychological disorders/issues/stresses (eg, presence of anxiety, depression, sleep disorder)
- Contextual factors that affect pain experience, engagement in treatment plan, and patient-provider relationship (eg, discrimination, structural racism, transportation, and work schedule)

Plan*

- For many pain conditions, use a multimodal approach incorporating nonpharmacologic therapy if appropriate (Chapter 77, "Pain Management," section on Nonpharmacologic Therapy)
- Drug therapy regimen including dose, route, frequency, and duration (see Chapter 77, Table 77-5)
- Referrals to other providers when appropriate (eg, primary care, rheumatology, orthopedics, behavioral health, gynecology, gastroenterology, dentistry)
- Follow-up plan (eg, primary care provider, specialist)

- Provide strict return precautions (ie, red flags, worsening or new symptoms)
    - Ensure updated list of referrals, including providers who take a variety of types of insurance or provide services on a sliding fee scale for individuals without insurance or who are unable to afford copayments.

Implement*

- Engage in a dynamic discussion with the patient, including patient education regarding all elements of the treatment plan (eg, purpose of multimodal treatment including lifestyle and dietary modification, medication administration, adherence), barrier mitigation, and functional treatment goals
- Use motivational interviewing and coaching strategies if the patient's confidence to engage in the treatment plan could reduce engagement
- Engage in collaborative problem-solving that acknowledges and adjusts for immovable structural, financial, occupational, and other barriers
- Schedule follow-up (eg, improved mobility, pain score, prevention of long-term use of OTC pain medications)

Follow-up: Monitor and Evaluate

- Self-monitoring for progress toward functional goal, meaningful reduction of pain symptoms, frequency and duration of pain, ability to cope with pain, and when to seek emergency medical attention
- Monitoring parameters related to efficacy (eg, mobility, pain score, missed days of activity such as work, or social events)
- Presence of adverse effects (eg, gastrointestinal issues such as ulcers or bleeding, rash)
- Patient adherence to treatment plan using multiple sources of information
- Frequency of reassessment should be dictated by the type and duration of pain

******Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Ask a friend or colleague to recall a painful experience from their past. Perform a pain symptom analysis with them using the PQRSTU method described in the chapter. Be sure to analyze each pain report if the pain experience involved multiple sources of pain. The goal of the interview should be to COLLECT information about their painful experience, ASSESS the pain, and classify it appropriately (eg, nociceptive somatic, nociceptive visceral, neuropathic). Ask yourself, could this patient be managed through self-care or is a referral required? This activity is intended to build pain symptom assessment skills and ability to identify pain etiology and pathogenesis.

INTRODUCTION

The International Association for the Study of Pain (IASP) defines pain as: "an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage."[1] Despite being a top reason patients access the medical system, many patients will attempt to manage their pain with nonprescription medications.[2,3] This gives unique opportunities for health professionals to improve the health, wellness, and medication use among patients experiencing pain.

EPIDEMIOLOGY AND ETIOLOGY

In 2016, approximately one in five people experienced chronic pain, with an estimated 8% of the US population experiencing high-impact chronic pain.[4] While the true incidence and prevalence is difficult to determine, painful disorders have a significant burden on our society. Chronic pain alone is estimated to cost the United States more than US$600 billion each year in medical treatment and lost productivity.[5] Unfortunately, our healthcare system has historically struggled to provide medical professionals with adequate education and training to sufficiently diagnose and treat people with pain.[6,7]

Headache and musculoskeletal disorders are two common etiologies of pain for which there are over-the-counter (OTC) treatment options available for patients. Globally, almost half of people with headache self-treat without a formal diagnosis.[8] This is concerning, as many of the medications commonly used to treat painful conditions carry serious side effects (ie, bleeding with nonsteriodal anti-inflammatory drugs [NSAIDs]). Furthermore, one study demonstrated approximately half of patients may not be aware of the potential side effects of their medication. Many patients are under the impression that OTC medications are safer or carry less risk than their equivalent prescription product.[9]

All healthcare professionals have a role to play in educating and assisting with the care of patients with painful disorders by screening for red flag symptoms (see Table e10-1) and referring patients to a primary care physician or specialist when appropriate. If a patient's presentation is appropriate to self-treat, health professionals can provide guidance on the most appropriate drug based on the patient's symptoms and encourage safe use (eg, dosing, duration of use, and monitoring parameters).

TABLE e10-1

Universal Red Flag Symptoms with Report of Pain

Red Flag Symptoms[a]
New onset numbness, weakness, vision changes, dizziness, or syncope
Sudden severe onset of pain
Persistent pain >3 days
Pain worsening despite treatment
Chest pain
Shortness of breath
Worsening pain with exertion
Bleeding disorder
Severe pain that diminishes ability to perform activity of daily living
Fever, nausea, vomiting, unintentional weight loss, or unexplained signs of systemic disorder
Suspected fracture
Pregnant

[a] Red flags are not a substitute for clinical judgment.

ANATOMY AND MECHANISM OF DISEASE

While pain can create much patient discomfort and disability, it also serves as an essential protective mechanism used to maintain homeostasis in the body. For a detailed review of the pathogenesis of pain, see Chapter 79, Pain Management. For the purposes of self-care, it is helpful to classify pain into subcategories to align treatment modalities.

Pain is often classified as nociceptive, neuropathic, or mixed (see Table e10-2). Nociceptive pain occurs in response to harmful or potentially harmful stimuli when signals are sent to the brain through the process of transduction, conduction, transmission, perception, and modulation. It is typically characterized as either somatic or visceral in nature. Somatic and visceral pain often respond to primary analgesics available OTC (eg, acetaminophen or NSAIDs), whereas neuropathic pain will often require a referral and evaluation for prescription analgesics. However, OTC products containing capsaicin or lidocaine are available and may be beneficial in the initial treatment of patients experiencing neuropathic pain (see Table e10-2).

TABLE e10-2

Classifications of Pain

Types of Pain	Patient Descriptions	Anatomy and Mechanism	Common Etiologies	Analgesics
Nociceptive somatic pain	• Sharp, dull, aching, worse with movement • Well-localized patients can often point directly to the location of pain.	• Occurs in response to harmful or potentially harmful stimuli. Signals are sent to the brain through the process of transduction, conduction, transmission, perception, and modulation. • Involves the skin, bone, joint, or soft tissue.	• Traumatic pain (cuts, scrapes, strains) • Arthritis pain • Musculoskeletal pain • Hemorrhoids	• Typically responds well to OTC analgesics such as acetaminophen or NSAIDs. • May require prescription analgesics
Nociceptive visceral pain	• Diffuse, gnawing, cramping, squeezing, pressure • Difficult for patients to localize the pain.	• Occurs in response to harmful or potentially harmful stimuli. Signals are sent to the brain through the process of transduction, conduction, transmission, perception, and modulation. • Can occur as a result of direct stimulation of afferent nerves due to tumor infiltration, distension of hollow viscus, infarct, or damage to soft tissue or viscera (ie, cardiac, gastrointestinal tract, genitourinary tract, lung).	• Menstrual cramps • Constipation • Gallstones • Kidney stones • Gastritis • Appendicitis • Cardiac conditions (ie, ischemia)	• May respond to OTC analgesics such as acetaminophen, or NSAIDs. • May require prescription analgesics
Neuropathic pain	• Burning, numbness, pins and needles, tingling, stabbing, shooting, electrical • Pain often starts in one area and radiates to another	Characterized by dysfunction or damage to the peripheral or central nervous system.	• Diabetic neuropathy • Postherpetic neuralgia	• Referral for medical evaluation. • May respond to OTC medications such as topical capsaicin or lidocaine. • Prescription medications including antidepressants and anticonvulsants are first-line treatment.

PATIENT CARE PROCESS

Collect Information

The clinician must collect information to characterize the pain, attempt to determine the etiology, and develop a treatment plan. If a patient has multiple sources of pain (ie, oral pain and headache), a pain symptom analysis should be conducted on each source of pain. A comprehensive symptom analysis utilizing the PQRSTU method is outlined in Table e10-3. Given that pain is subjective, information gathered from the patient will serve as the foundation for developing an appropriate treatment plan.[10]

TABLE e10-3

PQRSTU Pain Assessment

Letters	Descriptions	Assessment Questions	Examples
P	Precipitating factors	What brings on the pain or makes it worse?	– Position changes (standing, lying down, rolling over) – Activities (walking, playing with children) – Change in the weather – Stress
	Palliative factors	What helps relieve the pain?	– Heat, cold application – Position change (standing, lying down, rolling over) – Coping strategies (yoga, meditation, social activities) – Rest
	Previous treatment(s)	What have you tried in the past or present to manage the pain?	– History: Is it the same type of pain you have had before but more severe or totally new? – Medications (nonprescription, prescription, herbal, natural products)
Q	Quality	What does the pain feel like?	– See Table e10-2
R	Region	Where is the pain?	– Lower back – Jaw – Head
	Radiation	To where does the pain move?	– Moves from lower back down the leg – Moves from tooth to jaw
S	Severity	How much does the pain hurt?	– Ask the patient to rate their pain intensity on a scale of 0 to 10 with 0 equaling no pain and 10 equaling the worst pain imaginable
T	Temporal	When does the pain occur?	– Onset: Immediate or delayed? – Time of day: Morning or afternoon? – Frequency: Intermittent or persistent?
		Has it changed over time?	
U	You	How is the pain affecting you?	– Impact on patient’s mood, work, relationships – Activities of daily living

Data from Reference 11.

While a comprehensive symptom analysis collects most of the necessary information to assess a report of pain, other patient-related variables should be collected including current medications, vitamins, minerals, and herbal supplements. Information such as age and medical conditions (eg, renal or hepatic insufficiency, diabetes, immunosuppression, and pregnancy status) are essential to avoid potential medication-related issues in patients at elevated risk for adverse events.

Assess the Patient

The information gathered from the patient's self-report is considered the most reliable indicator of the presence, intensity, and impact of pain. General inspection of the pain site may be useful in determining the etiology (eg, swelling may indicate an inflammatory process) and appropriate treatment. Always keep in mind *the absence of physical signs of pain does not exclude* the possibility that the patient is experiencing pain. Other objective data such as physiologic or laboratory tests are unlikely to be available in the self-care setting and may not be useful in guiding treatment.

An attempt to determine the type of pain and its duration (acute vs chronic) should begin by assessing the patient's description of their painful condition. For the purposes of self-care, the clinician often needs to efficiently classify the pain, determine self-care eligibility, and consider what self-care treatments are available, accessible, and through discussion with the patient, a good fit (see Table 79-6 in Chapter 79, "Pain Management"; note that some products are available in both OTC and prescription formulations).

Three common examples of pain conditions that are frequently evaluated for self-care are headache, musculoskeletal disorders, and abdominal pain (eg, dysmenorrhea). Nonpharmacologic and pharmacologic treatment options are available for most painful conditions including headache (see Chapter 80, "Headache Disorders"), musculoskeletal disorders, and menstruation-related disorders (see Chapter 100, "Menstrual-Related Disorders"). A thorough discussion of the classification and management of pain is in Chapter 79.

Headache

When assessing a patient with a headache, the clinician must assess the information collected to determine if there are any red flag symptoms that may suggest a serious underlying disorder that would necessitate a medical referral (see Table e10-3). Headache disorders are discussed in-depth in Chapter 80.

Musculoskeletal Pain

The musculoskeletal system encompasses muscles, tendons, ligaments, cartilage, and bone. If possible, clinicians should assess the location (eg, lower back), signs, symptoms, and onset of the pain because these factors can allow further differentiation and classification of musculoskeletal disorders such as myalgias, tendonitis, bursitis, sprain, strains, or osteoarthritis (which is covered in detail in Chapter 110, "Osteoarthritis"). Recognizing that pain often serves as a protective mechanism within the body, the most important characteristic to assess with musculoskeletal injuries is whether the pain is acute or chronic in nature. A majority of minor acute musculoskeletal pain disorders will resolve with nonpharmacologic interventions and OTC analgesics. However, patients with musculoskeletal pain that persists for several days or worsens despite treatment should be referred to their primary care provider for further workup along with any patients experiencing red flag symptoms (see Table e10-1). Low back pain and osteoarthritis are common disorders that can be chronic in nature. These disorders are often complex and often require multiple treatment modalities including pharmacologic, physical, and/or interventional therapy.

Chest Pain

Although chest pain can be related to either a gastrointestinal or musculoskeletal etiology, it is also a symptom of serious and potentially fatal medical issues including cardiac conditions (eg, acute coronary syndrome) (see Chapter 34, "Acute Coronary Syndromes") or pulmonary disorders (eg, pulmonary embolism) (see Chapter 38, "Venous Thromboembolism"). Concern for cardiac, pulmonary, or other life-threatening issues should prompt immediate referral to the emergency department for full evaluation.

Abdominal Pain

Abdominal pain can be attributed to relatively benign causes such as gastroesophageal reflux disease (GERD) (see Chapter 50, "Gastroesophageal Reflux Disease") or constipation (see Chapter 54, "Diarrhea, Constipation, and Irritable Bowel Syndrome"). However, due to the difficulty of differentiating between these conditions in the community or ambulatory setting, these reports will often require referral for a full evaluation. However, abdominal pain related to dysmenorrhea can often be appropriately treated through self-care in the absence of red flags (see Table e10-1). Patients who are pregnant should consult with their obstetrician or primary care provider for evaluation and treatment of their pain. Dysmenorrhea amenable to self-care will often present as a cyclical pattern following the onset of menstruation and typically lasts several days. Menstruation-related disorders are discussed in-depth in Chapter 100.

Plan for Treatment or Referral

For most pain amenable to self-care, an attempt to maximize nonpharmacologic treatment prior to considering pharmacologic therapies should be made. An important tenet of medication decision-making for pain management is matching the mechanism of the medication to the type of pain (see Table e10-2). Often, this may require multimodal approaches to achieve optimal therapeutic benefit.

When considering drug therapy, clinicians should attempt to minimize the systemic exposure to medications by using topical agents containing ingredients such as methyl salicylate, menthol, lidocaine, or capsaicin when appropriate. The greatest opportunity to use these agents for self-care would be in the treatment of acute pain related to musculoskeletal disorders. If referrals are made, the clinician should attempt to follow-up with the patient and their provider to support the continuity of care.

Implement by Working With the Patient

Self-care encounters provide as an opportunity to engage in important discussions with the patient about the management of their pain. The practitioner should give the patient clear information about self-care strategies and instructions for the selected strategies in a format they can easily understand. Avoid using medical or advanced terminology. It can help to have templated infographics as well as worksheets that can be completed collaboratively with the patient during the encounter. Writing down the treatment plan and asking the patient to repeat back the information are two ways to ensure patients have the information needed to apply the plan. Be sure to address any administration, engagement, or cost barriers and discuss common adverse effects with the patient. Set clear and realistic “SMART” goals (eg, Specific, Measurable, Achievable, Realistic, and anchored within a Time Frame) to ensure that the patient has appropriate expectations about when to expect improvement.

One key aspect of education is how long a patient should be advised to self-treat for pain. In general, medications to treat pain should be used at the lowest effective dose for the shortest duration possible to minimize the risk of adverse reactions. While many patients believe the risks with medications such as NSAIDs only occur with long-term use, some studies have demonstrated that the cardiovascular and gastrointestinal risks associated with these agents may be elevated even within the first days to weeks of use.[11,12] If possible, pharmacists providing self-care recommendations should document these interventions in a patient’s profile and follow-up as appropriate.

Patient education should include the discussion of realistic functional pain goals and any potential activity and behavioral modifications. Several meta-analyses have indicated that exercise-based programs (eg, walking, strength training) could reduce pain and improve function for individuals with hip osteoarthritis,[13] general musculoskeletal pain,[14] and chronic back pain.[15,16] One study found that for every pound (0.45 kg) of body weight lost, the load on the knee is reduced fourfold.[17] Furthermore, adequate sleep and maintaining a consistent exercise routine decrease the frequency of headaches.

Follow-up by Monitoring and Evaluating Outcomes

Follow-up with a patient self-treating for pain should focus on the improvement of pain symptoms, functional outcomes, mobility, and participation in daily activities that are important to the patient. Patient self-monitoring and treatment can be enhanced by encouraging the patient to keep a pain diary to track symptoms, frequency, duration of pain, activities that reduced pain, and if and how the pain is affecting their daily life. Patients should be advised to seek emergency medical attention if symptoms progress or persist despite self-care. A key role of the pharmacist would also include monitoring for any adverse reactions if pharmacologic therapy was involved in the treatment plan.

It is important to recognize that historically, pain management has largely focused on resolving the intensity of pain (ie, What is your pain on a scale of 0-10?). While this has proved to be a simple and straightforward way to measure and track pain, it has the tendency to oversimplify a patient’s pain experience. Rather than focusing solely on a pain score, the best practice would be to also incorporate validated functional scales and the patient’s personal goals. Monitoring parameters for painful conditions should include function, mobility, pain score, missed days of activities such as work or social events, and impact of pain on physical function and mood. For example, behavioral goals evaluating a patient’s social engagement, such as attending family events or engaging in activities with friends, indicate how a patient may be coping with their disease. By focusing on functional and behavioral outcomes along with pain intensity, pharmacists and other primary-care professionals can better care for patients experiencing pain and make referral decisions based on solid evidence.

In most self-care situations, the frequency of reassessment will be dictated by the type and duration of pain. Ideally a patient’s pain should improve after treatment and resolve over several days. If a patient's pain does not improve despite treatment the patient should be referred to an appropriate clinician to have their condition fully evaluated.

CONCLUSION

Many patients experiencing pain seek to self-treat their condition. Clinicians can provide valuable care to these patients by performing a comprehensive pain symptom analysis. In the absence of red flags, an appropriate self-care plan can be developed, implemented, and monitored.

ABBREVIATIONS

GERD	gastroesophageal reflux disease
IASP	International Association for the Study of Pain
NSAIDs	nonsteroidal anti-inflammatory drugs
OTC	over-the-counter

SELF-ASSESSMENT QUESTIONS

1. A clinician should COLLECT which of the following *before* assessing a patient's report of pain?

   A. Pain symptom analysis (ie, PQRSTU)

   B. The patient's past medical history

   C. Physical examination findings

   D. All of the above

2. What is considered to be the most reliable indicator of the presence and intensity of pain?

   A. Vital signs

   B. Functional ability

   C. Patient's self-report of pain

   D. Caregiver assessment/report of pain

3. A patient's pain severity rating, such as "current pain is 4/10," should be placed in which of the following sections of a medical note?

   A. Subjective

   B. Objective

   C. Assessment

D. Plan

4. Asking a patient, "Describe what your pain feels like?" addresses which aspect of a PQRSTU Pain Assessment?

A. Q—Quantitative

B. Q—Quality

C. S—Severity

D. Y—You (Associated Symptoms)

5. Asking a patient, "What brings on your pain or makes it worse?" addresses which aspect of a PQRSTU Pain Assessment?

A. P—Precipitating

B. P—Palliative factors

C. P—Previous treatment(s)

D. None of the above

6. Which of the following statements is *incorrect* for the parameter of "PQRSTU" with which it is matched?

A. Temporal: "The pain comes and goes, lasts about 15 minutes, and occurs about four times a day."

B. Severity: "My pain is currently a 5 on a 0 to 10 scale."

C. Precipitating events: "Whenever I sit down, my pain skyrockets."

D. You (Associated Symptoms): "My pain has taken over my life and ruined all my relationships!"

E. Quality: "The pain started in my lower back, but now it hurt all over."

7. Which of the following is *not* a universal "red flag" symptom with a report of pain?

A. Shortness of breath

B. Pain improving with treatment

C. Fever with nausea

D. Headache for 4 days

8. A 30-year-old man reports pain in his back that moves down their leg and states, "It feels like it's on fire!" is *most likely* experiencing which type of pain?

A. Nociceptive somatic pain

B. Nociceptive visceral pain

C. Neuropathic pain

D. Conductive pain

9. A 52-year-old woman reporting aching pain in both her knees that is worse when she walks is *most likely* experiencing which type of pain?

A. Nociceptive somatic pain

B. Nociceptive visceral pain

C. Neuropathic pain

D. Conductive pain

10. A 23-year-old woman reporting cramping that typically occurs the same time every month following the onset of menstruation is *most likely* experiencing which type of pain?

   A. Nociceptive somatic pain

   B. Nociceptive visceral pain

   C. Neuropathic pain

   D. Conductive pain

11. A person is reporting severe, diffuse right flank pain that you suspect could be appendicitis. If true, he/she is *most likely* experiencing which type of pain?

   A. Nociceptive somatic pain

   B. Nociceptive Visceral pain

   C. Neuropathic pain

   D. Conductive pain

12. Which of the following OTC medications may benefit a patient experiencing mild, localized neuropathic pain related to postherpetic neuralgia treated over a year ago?

   A. Ibuprofen

   B. Acetaminophen

   C. Aspirin

   D. Lidocaine

13. LS is a 56-year-old man who presents to your pharmacy today asking what medication he can take to relieve his new-onset chest pain. What would be the best plan for LS?

   A. Educate the patient that the pain is likely self-limiting and will resolve in a few hours.

   B. Refer the patient to the nearest emergency department for further evaluation.

   C. Recommend ibuprofen 200 mg every 4 to 6 hours as needed for pain.

   D. Advise the patient to call his primary care provider.

14. A 19-year-old woman presents to your pharmacy reporting mild cramping in her abdomen that typically occurs following the onset of menstruation. She asks the pharmacist what medication she can take to help with the pain. She reports no known drug allergies, and the only medication she takes regularly is an estrogen and progestin combination oral contraceptive pill (ethinyl estradiol and norgestimate). What would be the best plan for treatment or referral for her?

   A. Refer the patient to her primary care physician for treatment

B. Recommend she apply a thin film of capsaicin 0.1% cream to the affected areas three to four times daily

C. Recommend ibuprofen 200 mg every 4 to 6 hours as needed for pain

D. Refer the patient to the nearest emergency department for immediate evaluation

15. US is a 62-year-old woman experiencing stiffness in her hips and knees over the past several months. She plans to exercise and hopes to lose weight but calls your pharmacy asking if there is medication available over-the-counter that may improve her pain. She reports having an anaphylactic reaction to aspirin. What would be the best plan for treatment or referral for US?

A. Refer the patient to the nearest emergency department for further evaluation

B. Recommend ibuprofen 200 mg every 4 to 6 hours as needed for pain

C. Recommend acetaminophen 1,000 mg every 4 hours as needed for pain

D. Recommend acetaminophen 1,000 mg every 6 hours as needed for pain

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** It is necessary to gather patient information from a pain symptom analysis, medical history, and physical examination to properly assess a report of pain. See the “Collect Information” section for more information.

2. **C.** The information gathered from the patient’s self-report is considered the most reliable indicator of the presence and intensity of pain. See the “Assess the Patient” section for more information.

3. **A.** Given that pain is always subjective, the most appropriate place in a medical note would be the subjective section. See the “Collect Information” section for more information.

4. **B.** Asking the patient what their pain feels like is describing the quality of their pain. See Table e10-3 for more information.

5. **A.** Asking the patient what brings on their pain or makes it worse is identifying precipitating factors related to their pain. See Table e10-3 for more information.

6. **E.** The patient’s statement that their pain started in their back but is now all over best describes the region and radiation of their pain. Therefore, matching quality to this statement would be incorrect. See Table e10-3 for more information.

7. **B.** Pain improving with treatment is not a universal “red flag” listed in Table e10-1. All of the other options are correct “red flag” symptoms.

8. **C.** The patient is describing a burning sensation, which is likely indicative of neuropathic pain. See Table e10-2 for more information.

9. **A.** The patient is describing aching in both knees, which likely involves the bone, joint, or soft tissue. This pain would be best classified as nociceptive somatic pain. See Table e10-2 for more information.

10. **B.** The patient is describing pain that is likely related to menstrual cramps given that it occurs at the same time every month following the onset of menstruation. This pain is best classified as nociceptive visceral pain. See Table e10-2 for more information.

11. **B.** The patient is describing pain that is highly suspicious for appendicitis and likely nociceptive visceral pain. See Table e10-2 for more information.

12. **D.** Neuropathic pain may respond to medications such as topical capsaicin or lidocaine, which are available over-the-counter. See Table e10-2 for more information.

13. **B.** New-onset chest pain is a “red flag” symptom with report of pain. The concern for cardiac issues requires referral to the emergency department for evaluation. See the “Assess the Patient” section for more information.

14. **C.** Pain caused by menstrual cramps may respond to OTC analgesics such as acetaminophen or NSAIDs such as ibuprofen. Choices A and D are not

the best plan as the patient does not have any “red flag” symptoms that would preclude self-care. Choice B is not correct as capsaicin is not the most efficacious medication for this type of pain and often takes days to weeks to provide pain relief when used appropriately. See Table e10-2 for more information.

15. **D.** The patient is likely describing pain caused by osteoarthritis. This pain typically responds well to OTC analgesics such as acetaminophen. Choice A is not the best plan as the patient does not have any “red flag” symptoms that would preclude you from providing care. Choice B is incorrect as the patient reported an anaphylactic reaction to aspirin. Patients with a history of aspirin intolerance should be advised to avoid all aspirin- and NSAID-containing products. Choice C is incorrect given that the dose exceeds 4 g/d of acetaminophen and is, therefore, potentially hepatotoxic. See the “Collect Information and Plan” section of the Patient Care Process box for more information.

Chapter e11: Minor Ophthalmic Disorders

Jared Ostroff

KEY CONCEPTS

KEY CONCEPTS

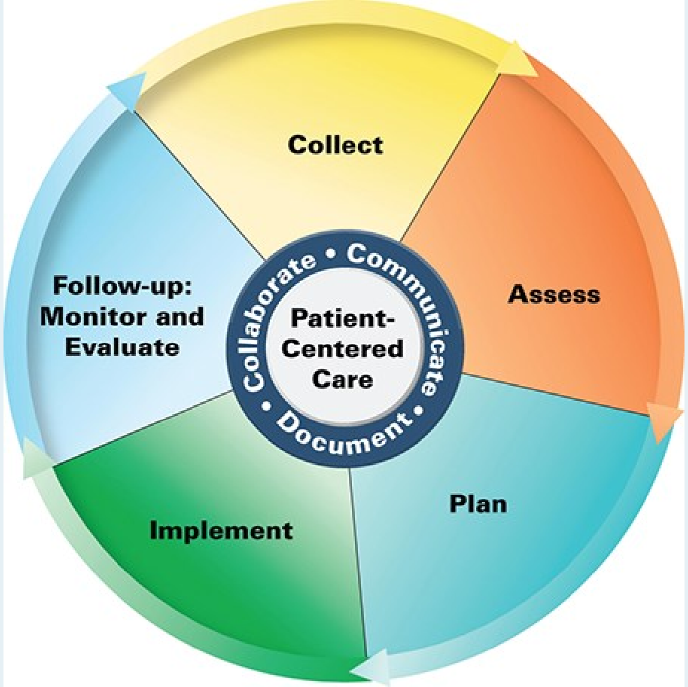
① Pharmacists are often the first healthcare provider that patients will seek with various eye complaints.

② It is crucial to understand the various products available over-the-counter (OTC) to provide appropriate recommendations.

③ Healthcare professionals should also be familiar with eye conditions that do require referral to a medical provider for further evaluation.

PATIENT CARE PROCESS

Patient Care Process for Eye Complaints



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Collaborate • Communicate • Document •
Patient-Centered Care

Collect

- Patient characteristics (eg, age, sex, pregnancy status)
- Patient medical history (personal and family)

- Social history (eg, tobacco/ethanol use)
- Current medications including prescription, OTC aspirin/NSAID use, herbal products, dietary supplements
- Objective data
    - Appearance of ophthalmic redness, inflammation, or any other signs

Assess

- Appropriateness for self-care (eg, red flags that would indicate referral or higher level of care such as bleeding or failed previous attempts at treatment)
- Presence of anything physically blocking the eye or eyelid
- Presence of common provoking factors (eg, recent drug use, new medications, changes in weather, history of allergies)
- Ability/willingness to administer eye drops correctly (eg, health literacy, age of patient)
- Ability/willingness to pay for OTC options that are not covered by insurance
- Ability/willingness to follow-up with provider if symptoms do not improve

Plan[*]

- Drug therapy regimen including specific eye drops and/or medication(s), dose, route, frequency, and duration
- Monitoring parameters including efficacy (eg, resolution/improvement in symptoms); frequency and timing of follow-up
- Patient education (eg, purpose of treatment, medication administration technique)
- Self-monitoring for resolution of symptoms
- Referrals to other providers when appropriate (eg, primary care provider, urgent care)

Implement[*]

- Provide patient education regarding all elements of treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence
- Encourage patient to return with any questions or contact their provider if their complaint worsens

Follow-up: Monitor and Evaluate

- Resolution of eye symptoms (eg, redness, pain, excessive tearing)
- Presence of adverse effects (eg, burning, stinging)
- Patient adherence to treatment plan
- Reevaluate if necessary

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

Design a list of questions for a patient who is presenting with complaints of dry eyes. Which medications and/or disease states would you screen when reviewing their medication lists? What would be your initial OTC recommendation for symptom relief? This activity will develop your skills with collect, assess, and plan within the Patient Care Process.

INTRODUCTION

① When it comes to ophthalmic complaints, there are many considerations and other causes to rule out prior to making a pharmacologic recommendation. Patients will sometimes present in the pharmacy or primary care setting with dry eyes, burning eyes, or obstructed vision, or for help selecting appropriate contact lens solutions. While patients may seek a quick cure, the healthcare professional must also realize that a full assessment is encouraged for each patient complaining of symptoms to determine if it is appropriate to use nonpharmacologic or pharmacologic treatments that are available without a prescription or refer to another provider.

This chapter reviews common eye complaints and how to make evidence-based recommendations on management.

DRY EYES

Collect. Dry eye disease, or keratoconjunctivitis sicca, is one of the most common complaints when patients visit the eye doctor, and its prevalence is estimated between 7% and 33%.[1] Risk factors for the development of dry eyes include increasing age and female sex.[2] While onset of dry eyes is often unpredictable, it may correlate with exposure to various changes in environment and current medications.

Patients with dry eyes may present with or without redness of the eyes with various complaints that will need a review of their current medical history and other predisposing factors. Factors such as weather, current medications, recent exposure, and previous experience with the condition are essential in triage and making recommendations for therapy.

Assess. The first step in evaluating a patient with dry eyes is to evaluate the complaints and medical history including any current medications or environmental triggers. Patients may not always recognize that environmental factors could play a role so it is essential to ask for that information. Since dry eyes may be caused by a variety of medications, perform a medication reconciliation with the patient's current medication list. Some of the medications to check for include antihistamines, decongestants, antidepressants, and hormone replacement therapy.[3] While this is not the only mechanism that can cause dry eyes, medications are frequently implicated. If offending medications are identified during reconciliation, advise the patient to stop using if appropriate and recommend an alternative product that would minimize the potential for dry eyes to return.

Plan. Once a thorough medication reconciliation is complete, rule out for any red flags such as complaints of any discharge, blurry vision, or difficulty with vision. Patients with those symptoms should be referred to a medical provider for further evaluation.

Implement. If there are no red flags or urgent symptoms needing further evaluation, the choice of best initial option should be discussed with the patient. A number of factors contribute to selection of an initial treatment option. These may include cost, dosage form (suspension vs solution), administration times, previous experience with a product, and any potential drug or nondrug allergies.

② When considering OTC treatment for dry eyes, the first-line recommendation is artificial tears, which may include cellulose, polyethylene glycol, and a preservative. Each of these ingredients have a specific role in dry eye treatment and many come in a variety of forms such as liquid, gel, and ointment. Preservative-free forms are also available; these are preferred in patients who wear contact lenses.

Artificial tears are evidence based and have been proven to improve patient symptoms.[4] These products include cellulose ethers, such as hydroxyethylcellulose, carboxymethylcellulose, and hydroxypropyl methylcellulose. Other ingredients used in dry eyes include white petrolatum to assist with lubrication of the eye. There are several randomized trials showing efficacy with artificial tears; anecdotal reports also show that they are effective in keeping the eyes lubricated.[5] A starting dose for artificial tear administration is one drop in each eye, three to four times a day. Many patients experience improvement within 1 to 2 days after administration; however, it may take a week or longer in some cases. Depending on the dosage form, patients may want to consider administration in the evening. Dosage forms such as ointments or gels have specific application instructions and may cause a temporary visual disturbance while the medication is being absorbed.

3 **Follow-up.** If relief is not achieved within 1 to 2 days, a referral to the patient's primary care physician or urgent care is encouraged.

BLEPHARITIS

Collect. Blepharitis is a common eye condition characterized by inflammation of the eyelid margin, which may also present with crust on the eyelid and itchiness associated with the patient complaints.[6,7] Patients with this condition may have been diagnosed as a child and present seeking OTC symptom relief. Blepharitis is often considered to be permanent and it is crucial for patients to understand it as a chronic condition as they approach with any questions. The chronic nature of blepharitis may make the conversation difficult when discussing potential treatment options. If left untreated, complications from blepharitis include the formation of a stye (hordeolum, a bacterial infection of an oil gland in the eye) or chalazion (cyst in eyelid caused by blocked oil gland).

While blepharitis is one of the most common eye disorders and patients may present with questions, the incidence is difficult to determine. A study of patients with chronic blepharitis noted that the mean age of patients was 50 years.[7] A separate informal survey of 5,000 US adults demonstrated that symptoms associated with blepharitis are common and that younger adults report symptoms more frequently.[8]

Potential causes of blepharitis include contact, allergen, or another type of skin condition.

Assess. While there are many potential causes for blepharitis, one is an overexpression of the bacteria naturally present in the eyelid. This normally includes *Staphylococcus aureus* and coagulase-negative staphylococci.[9,10] Other risk factors for the development of blepharitis include dry eyes, demodex folliculorum, rosacea, and use of isotretinoin.[9]

Patients with blepharitis report symptoms of swollen itchy eyelids, crusting or matting of eyelashes upon awakening, blurred vision, and "pink eyes" (conjunctivitis). While the patient may be requesting immediate relief, it is important to assess for presence of other red flags to ensure optimal treatment.

2 **Plan.** Treatment for patients with blepharitis prior to referral for physician care include topical hygiene products available OTC. The healthcare professional should keep in mind the patient's manual dexterity and visual acuity when instructing them on proper self-care of blepharitis. When making recommendations for symptom relief the following products may be helpful:

- Warm compresses
- Eyelid cleansing
- Artificial tears

Implement. Apply a warm compress to the eyelids for several minutes in order to loosen the crust that may have been building up on the eyelid. When counseling patients it is important to encourage them to use warm compresses and to avoid using compresses that are too hot as to avoid burning their eyes. Eyelid cleansing is described as brief massage on the eyelids. Instruct the patient to gently rub the base of the eyelashes using a commercially available eyelid cleaner, cotton ball, or clean fingertip.

If the patient has any visual or other difficulties it may be best to refer them for further care. When performed several times weekly, eyelid cleansing may help to prevent the eyelids from becoming inflamed. Because of potential aqueous tear deficiency associated with blepharitis, artificial tears may improve symptoms when used in conjunction with eyelid cleansing and warm compresses.

3 **Follow-up.** Patients with suspected blepharitis who do not achieve relief within a few days should be referred for medical evaluation.

CONJUNCTIVITIS

Collect. Conjunctivitis, also known as "pink eye," refers to the inflammation of the conjunctiva within the eye. This thin clear membrane can, at times, become inflamed and result in various presenting symptoms. Conjunctivitis affects approximately six million people annually in the United States with a cost estimated between $300 and $800 million.[11]

Assess. Symptoms of conjunctivitis may include a pink color in the whites of the eye(s), increased tear production, itching, blurred vision, irritation, and crusting of the eyelids usually in the early morning upon awakening. There are various types of conjunctivitis including bacterial, viral, allergic, and contact conjunctivitis. Table e11-1 lists the various types of conjunctivitis that may be seen in the community; however, other types do exist but will not be covered in this section. While bacterial conjunctivitis is more common in children, viral remains the most prevalent among all age groups and typically presents in the winter months from December through April. One of the key clinical features that may help differentiate referral versus self-treatment is the presence or absence of discharge. Bacterial conjunctivitis may present in patients with discharge, which would therefore prompt referral to the provider for prescription treatment. Red flags that should prompt referral for further evaluation could include reduction of visual acuity, an inability to open his/her eye, or severe headache associated with the onset of symptoms.

TABLE e11-1

Key Characteristics of Bacterial, Viral, and Allergic Conjunctivitis

Etiology	Condition	Onset	Symptoms	Options
Bacterial	Acute	Acute	Tearing, lid crusting	Symptomatic treatment, refer to provider
	Chronic	Chronic	Lid crusting	
Viral	Adenoviral	Acute	Tearing, lid crusting upon awakening	Symptomatic treatment, cold compresses
	Herpetic	Acute	Tearing	
Allergic	Seasonal	Seasonal	Itching, tearing	Symptomatic relief (antihistamines, mast cell stabilizers, decongestants, cold compresses)
	Vernal	Seasonal	Itching, mucous discharge	
	Giant Papillary	Acute	Itching, contact lens intolerance, mucous discharge	

Plan. Viral conjunctivitis is highly contagious; it can be spread by touching other individuals or objects. It is the most common type of conjunctivitis and may also result in many pharmacist visits for symptom relief. Similar to any other virus, the infection will need to run its course over time, which may be burdensome to the patient. Generally, viral conjunctivitis will resolve 2 to 3 weeks after initial symptom presentation, during which time patients may have consistent morning "crust" upon awakening.

Allergic conjunctivitis occurs due to contact with external triggers such as dander, pollen, and other environmental triggers. It affects up to 40% of the population and many allergy sufferers present with seasonal allergic conjunctivitis annually during allergy season.

② **Implement.** Treatment for viral, allergic, and contact conjunctivitis usually includes OTC self-care products available from the pharmacy. A previous study was conducted looking at prescription versus OTC treatment for presumed viral conjunctivitis.[12] This study, conducted in Brazil, ultimately found that treatment with a topical steroid was not superior to artificial tears in acute viral conjunctivitis. Healthcare professionals must evaluate each patient individually and with consideration of presenting signs and symptoms. Product recommendations should take into account the specific symptoms that the patient is reporting. Many OTC products contain a combination of various ingredients which may not be helpful to the patient.

OTC products for viral and bacterial conjunctivitis containing a topical decongestant/antihistamine may be used 1 to 2 drops in each eye four times daily as needed plus/minus eye lubricant drops 1 to 2 drops every 1 to 6 hours as needed. Allergic conjunctivitis may respond to the previously stated agents but another possibility is the use of mast cell stabilizers and/or antihistamines. Healthcare professionals should also explain that while the patient may experience some relief, the medication will not reduce the virus activity or help the eye heal any faster. Cold compresses are another option to help with symptom relief and can be recommended in almost all cases.

③ **Follow-up.** Patients should also be made aware that the symptoms may worsen 3 to 5 days from initial onset before starting to resolve but if they are experiencing any loss of vision or red flag symptoms, it is advisable to seek out their medical provider for further evaluation.

CONTACT LENS CARE AND COMPLICATIONS

An estimated 30 million people in the United States wear contact lenses.[13] The majority are women and the average age worldwide is 31 years old. While pharmacies in the United States generally do not sell contact lenses, patients often present with questions for the pharmacist about contact lens care and troubleshooting various problems. Between 40% and 90% of contact lens wearers do not properly follow the care instructions, putting them at risk for various eye infections, including keratitis, corneal abrasions, and corneal infiltrates.[14,15] Cleaning and maintenance of contact lenses is critical to ensuring safe and effective use.

Collect. To provide recommendations to patients who wear contact lenses, healthcare professionals need information about the wide variety of available styles and options. While some patients prefer daily contact lenses that may be disposed of, others may select reusable contact lenses that require cleaning every evening overnight. Some patients may also prefer to use contact lenses that are approved for overnight use.

The American Optometric Association has many recommendations for the successful use of contact lenses. Some of the recommendations include proper hand hygiene, appropriate storage conditions, and use of fresh solution daily. Products are available for ensuring adherence to these recommendations.

Assess. Patients may present to the pharmacy requesting advice and/or assistance with selection of contact solution, saline, and other nonpharmacologic treatment. Before recommending self-care products, the health professional should ensure that the patient is following proper hygiene procedures and is handling contact lenses in accordance with the manufacturer instructions. General recommendations that can be provided include the following:

- Wash hands with soap and water, and dry completely before handling contact lenses.
- Avoid sleeping in contact lenses unless such use is approved by medical provider.
- Avoid showering in contact lenses to limit the amount of water available to enter the lenses.
- Use only fresh contact solution each time the contact lenses need to be cleaned.
- Rinse your contact lenses with contact lens disinfecting solution as instructed by the manufacturer. Do not use saliva or water to attempt to clean your contact lenses

② **Plan.** Various solutions and disinfecting agents are available without a prescription. Regardless of the brand of solution chosen, healthcare professionals should advise the patient to clean their hands each time they handle contact lenses to reduce the chances of infection. Before selecting any contact lens solution, patients should be encouraged to communicate with their eye professional to see if a specific solution is recommended based on the lens material. Patients should also be sure to check the expiration dates of solutions and cleaners in their homes and discard expired products.

Implement: A multipurpose solution is an all-in-one product that cleans and disinfects soft contact lenses. It is the most commonly used solution among contact lens wearers and is generally the most affordable. The following recommendations can be provided safely to patients wishing to use multipurpose solution[16]:

- Store contact lenses in fresh solution each time they are cleaned
- Rinse the contact lens storage case in fresh solution every day
- Store the clean case upside down in order to prevent microbial growth

- Change contact lens case at least every 3 months, potentially more often depending on specific manufacturer instructions

Hydrogen peroxide-based systems may be used in the case of an allergy to an ingredient in the multipurpose solution, or simply for patient preference. These solutions are preservative free and thus may represent an appeal to various patients. They are available OTC and come with their own container that the contact lenses must be placed in prior to cleaning. It is important to inform the patient not to use a different case other than what's provided. Changing cases and utilizing the hydrogen peroxide solution in a different case may result in significant eye burning. When using a hydrogen peroxide-based solution, patient must wait at least 4 to 6 hours before removing the contact lens and inserting them into the eye. This allows for the appropriate amount of time, during which the hydrogen peroxide is converted to saline.

Follow-up. Saline solution and daily cleansers are sometimes used on an as-needed basis if the patient believes they have something stuck in their eye or if their vision has turned slightly blurry from the lens. It is important to note that saline does not disinfect the contact lens and thus should not be recommended without another form of cleansing/disinfecting solution.

Patients inquiring about eye care with contact lenses may also ask about eliminating red eye, dry eyes, and other eye conditions. Patients with contact lenses should not be using OTC products that include relief for red eyes or any product with preservatives. These products contain chemicals that may be harmful when used over the long-term.[17,18] Encourage patients to use products that are preservative-free to ensure there are no harmful chemicals that could damage the eye and/or the contact lens. If using disposable contact lenses, patients should be instructed to dispose of them at the recommended duration. Patients should also be advised to use makeup and other products that are marked safe for contact lens use.

CONCLUSION

Healthcare professionals are well positioned to help patients with many common eye complaints, including contact lens challenges. There are a variety of products available OTC that may cause confusion when deciding whether to self-treat or seek out further medical attention. By conducting a thorough assessment of each patient and utilizing the patient care process, the healthcare professional can make the most evidence-based recommendation and provide relief to the patient.

SELF-ASSESSMENT QUESTIONS

1. What is one of the most common eye complaints?

A. Dry eye disease

B. Wet eye disease

C. Red eyes

D. Excess eye lash growth

2. Patients may be more likely to have dry eyes if they are taking which ONE of the following medications?

A. ACE inhibitor

B. Leukotriene inhibitor

C. Antihistamine

D. Analgesic

3. A potential red flag that would prompt a referral to a doctor or urgent care facility would include:

A. Limited budget.

B. Ocular discharge.

C. Itching of the eye.

D. Excess tearing.

4. A patient would like a recommendation for dry eyes. After consultation and thorough medication screening you decide it is appropriate to make a recommendation. Which of the following choices would be the BEST initial option for treatment of dry eyes?

A. Petroleum jelly

B. Astringent drops

C. Antihistamine drops

D. Artificial tears

5. When counseling a patient on the expectations for relief when treating dry eyes, what would be an appropriate amount of time to wait until seeking further care if there is no improvement?

A. 3 to 4 weeks

B. 6 to 7 days

C. 1 to 2 days

D. 6 to 8 weeks

6. A patient presents for consultation and evaluation with an eye complaint. They report that for the past 2 days they have woken up with a “crust” around their eyelids and need to rinse their eyes as soon as they wake up. Which eye condition does this most closely relate to?

A. Blepharitis

B. Dry eye disease

C. Glaucoma

D. Cataracts

7. All of the following are appropriate OTC recommendations for Blepharitis except:

A. Warm compresses.

B. Eyelid cleansing.

C. Topical NSAIDs.

D. Artificial tears.

8. Which of the following disease states include complaints of pink color in the eyes, increased tear production, and crusting of the eyelids in the morning?

A. Dry eyes

B. Macular degeneration

C. Diabetic macular edema

D. Conjunctivitis

9. Various types of conjunctivitis exist and patients will require education on the various differences. Which one of the following types of conjunctivitis is NOT able to be treated with OTC products?

A. Viral

B. Allergic

C. Contact

D. Bacterial

10. Antihistamines would be most appropriate in which one of the following types of conjunctivitis?

A. Viral

B. Allergic

C. Contact

D. Bacterial

11. Which of the following statements regarding contact lens wearers is true?

A. Between 40% and 90% of contact lens wearers do not follow the care instructions.

B. Cleaning and maintenance at least monthly is required for optimal care of the lenses.

C. Contact lenses are available to all patients without a prescription.

D. Daily disposable contact lenses require cleaning every night to ensure optimal use.

12. All of the following recommendations should be followed when using multipurpose solution except:

A. Store contact lenses in fresh solution each time they are cleaned.

B. Rinse the contact lens storage case in fresh solution every day.

C. Store the clean case upside down in order to prevent germs.

D. Utilize boiling water for cleaning the storage case every other day.

13. When is it appropriate for a contact lens wearer to use saline solution to rinse their eyes?

A. It is never appropriate to use saline solution when wearing contacts.

B. Saline solution is appropriate on an as-needed basis if the patient believes something is in their eye.

C. Saline solution should be heated up to ensure all bacteria have been removed prior to using.

D. Contact lens wearers may utilize saline solution in place of multipurpose and/or cleansing solution as frequently as needed.

14. When is it appropriate for a patient who wears daily disposable contact lenses to reuse them the following day?

A. Contact lenses may be reused as long as it is within 24 hours from the time the package is open.

B. Daily contact lenses are meant for single use only and should never be worn the following day unless advised by a healthcare professional.

C. Patients who wear daily contact lenses may reuse their contacts after ensuring they are soaked overnight in the appropriate solution.

D. Patients who wear daily contact lenses may reuse them until there is visible deterioration in the lens. This will allow for significant cost savings.

15. A patient presents with complaints of itchiness and tearing in both eyes since yesterday. No current medications. Denies any crusting around eyes when waking up in the morning. What would be the most appropriate diagnosis and treatment for this patient given the information provided?

A. Bacterial infection: Refer to healthcare provider for assessment

B. Viral infection: Refer to healthcare provider for assessment

C. Seasonal allergies: Recommend OTC topical agent to help with symptom management

D. Allergic reaction: Recommend OTC oral diphenhydramine every 6 hours as needed

SELF-ASSESSMENT QUESTION-ANSWERS

1. **A.** Dry eye disease is one of the most common complaints. Its prevalence has been estimated between 7% and 35%.

2. **C.** Use of antihistamines including diphenhydramine and loratadine results in dry eyes, dry mouth, constipation, and other anticholinergic properties. Patients should be encouraged to use them for the shortest duration necessary.

3. **B.** Ocular discharge requires prompt referral to an eye specialist or urgent care as it may require further differential diagnosis and appropriate treatment with prescription medication.

4. **D.** The most appropriate initial option would be artificial tears now. If the patient returns with other complaints such as redness or if they are reporting seasonal allergies, other options such as an antihistamine may be appropriate at that time.

5. **C.** Artificial tears should work relatively quickly to help relieve dry eyes. If there is no relief after 1 to 2 days the patient should be instructed to seek further care from their physician.

6. **A.** Blepharitis is a common eye disorder that commonly results in inflammation of the eyelid margin and may result in the patient complaint of "crust."

7. **B.** Topical NSAIDs are not available OTC and will not likely improve the symptoms or disease progression. Patients with blepharitis should be advised to keep their eyelids clean and utilize other OTC options.

8. **D.** Conjunctivitis, also known as pink eye, occurs when the conjunctiva in the eyes become inflamed and may result in various complaints from patients.

9. **D.** Bacterial conjunctivitis will require treatment with antibiotics from a medical office or clinic. While symptomatic recommendations can be made to help the patient, they should be referred to a doctor for further care.

10. **B.** As the origin of the conjunctivitis was stated to be "allergic" in nature, an OTC antihistamine would be appropriate for initial treatment of the patient's complaint.

11. **A.** It has been reported that up to 90% of contact lens wearers do not follow the care instructions. This could include not maintaining proper hygiene, improper storage conditions, or potentially reusing disposable contact lenses.

12. **D.** It is only appropriate to use contact solution that is pre-packaged and available from a pharmacy or other store. Boiling water is not an appropriate substitute for contact solution.

13. **B.** Patients can be counseled that if something is in their eye or they believe that their contacts have become dry to utilize saline solution as needed.

14. **B.** Patients who are prescribed wearing daily disposable contact lenses should be advised to discard the lenses at the end of the day, every day.

Disposable contact lenses are not indicated to be worn for more than 1 day. If the patient would like something that they could reuse on a daily basis, ensure appropriate referral to eye health professional.

15. **C.** The patient is presenting without the key complaint of crusting around the eyes. Generally speaking, when crusting around the eyes is present we are considering either bacterial or viral conjunctivitis. Since the patient is presenting with itching in both eyes and tearing, this could indicate seasonal allergies, with appropriate recommendation the patient would likely see relief in a matter of hours.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e >

Chapter e12: Minor Otic Disorders (Cerumen Impaction, Otitis External)

Lea S. Eiland

KEY CONCEPTS

KEY CONCEPTS

① The most common pathogens in acute otitis externa (AOE) are *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

② Topical antimicrobials are the medication and route of choice for the treatment of AOE.

③ Systemic antimicrobials are not warranted for the initial treatment of diffuse, uncomplicated AOE.

④ Pain should be assessed in all patients and therapy recommended based upon severity.

⑤ Appropriate counseling points for otic administration of medication should be provided to each patient.

⑥ Cerumen production is a naturally occurring process of the body.

⑦ Cerumen impaction may cause discomfort, itching, hearing loss, or tinnitus.

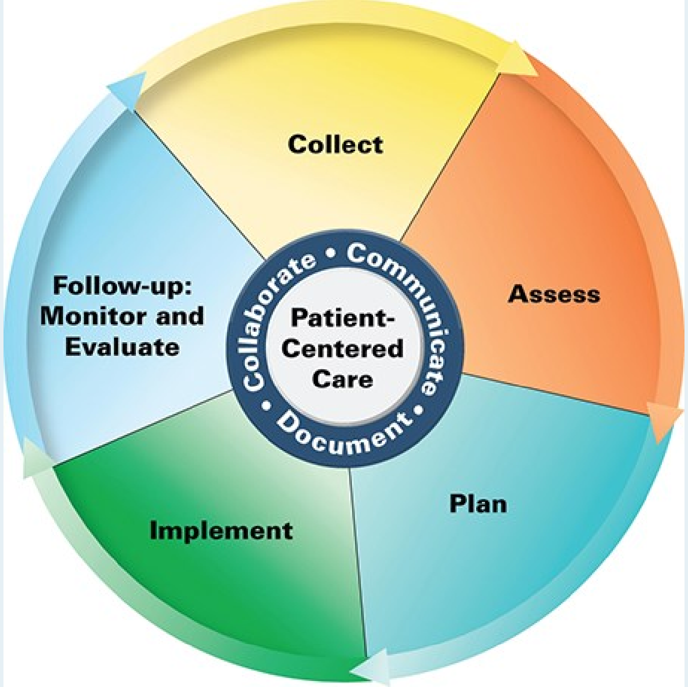
⑧ Cotton swabs should not be used as they can worsen cerumen impaction or cause trauma to the tympanic membrane.

⑨ Home-treatment options for cerumen impaction include cerumenolytic agents and/or irrigation.

⑩ Foreign objects such as pen caps, tweezers, or paper clips should not be inserted in the ear canal.

PATIENT CARE PROCESS

Patient Care Process for Acute Otitis Externa (AOE)



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient characteristics (eg, age)
- Patient medical history (eg, history of diabetes mellitus, radiation, eczema, immunocompromised, perforated tympanic membrane, tympanostomy tube, hearing aids)
- Medication allergies (eg, neomycin)
- Social history (eg, water exposure)
- Subjective/objective data: Signs and symptoms of AOE (eg, otalgia, itching, fullness, hearing loss, pain, tenderness, trauma)

Assess*

- History of diabetes mellitus, past radiation, immunocompromised states such as HIV, AIDS, chemotherapy, or ototoxicity
- Presence of tympanostomy tube or perforated tympanic membrane
- History and severity of pain
- Risk of adverse effects from topical medication
- Patient adherence
- Cost of medication

Plan*

- Select a topical antimicrobial therapy with or without accompanying steroidal agent; options include specific medication(s), dose, route, frequency, and duration provided in Table e12-1
- Select pain medication (nonprescription or prescription)

- Educate patient (eg, purpose of treatment, drug-specific information, medication administration technique for otic preparations, avoidance of water sports for 7-10 days)
- Recommend self-monitoring for resolution of signs and symptoms
- Recommend prevention strategies for AOE (eg, acidifying ear drops, thorough drying of the ear canal)
- Make referrals to other providers when appropriate (eg, dermatologist, otolaryngologist)

Implement*

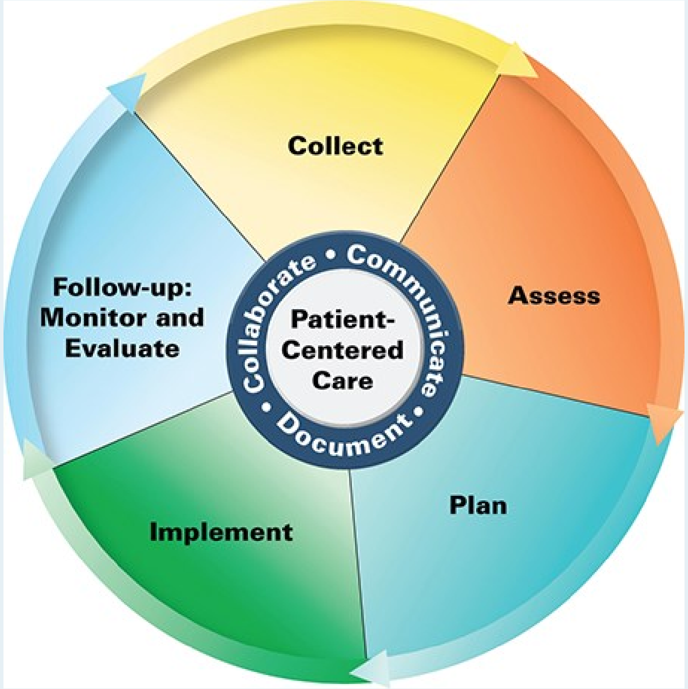
- Provide patient education regarding all elements of the treatment plan and medication administration technique
- Use motivational interviewing and coaching strategies to maximize adherence

Follow-up: Monitor and Evaluate*

- Signs and symptoms improvement (eg, otalgia, itching, fullness, pain, tenderness) within 48-72 hours, symptom resolution may take up to 2 weeks
- Presence of adverse effects (eg, allergic reaction to topical medication)
- Patient adherence to treatment plan using multiple sources of information

**Collaborate with patient, caregivers, and other healthcare professionals.*

Patient Care Process for Cerumen Impaction



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Collaborate • Communicate • Document •
Patient-Centered Care

Collect

- Patient characteristics (eg, age)

- Patient medical history (eg, immunocompromised state, diabetes mellitus, prior radiation, nonintact tympanic membrane, ear canal abnormalities, hearing aids, dermatologic disorders)
- Social history (eg, ear-cleaning habits)
- Current medications including anticoagulant use
- Subjective data: signs and symptoms of impaction (eg, otalgia, fullness, itching, tinnitus, cough, vertigo, hearing loss)
- Patient communication abilities

Assess*

- History of diabetes mellitus, immunocompromised state, radiation, or ear canal anatomical abnormalities
- Presence of tympanostomy tube or perforated tympanic membrane
- Current hearing aid use
- Limited expressive language (eg, younger child or cognitively impaired patient)
- Patient adherence
- Cost of medication

Plan*

- Decide if self-treatment is an option
- Select a cerumenolytic agent and/or irrigation agent for use
- Patient education (eg, purpose of treatment, medication administration, irrigation technique)
- Self-monitoring for resolution of signs and symptoms of impaction
- Referral to general physician or otolaryngologist if the patient has modifying factors for treatment

Implement*

- Provide patient education regarding all elements of the treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence

Follow-up: Monitor and Evaluate*

- Symptom resolution (eg, otalgia, pain, fullness, itching, tinnitus, cough, vertigo)
- Improvement in hearing loss
- Presence of adverse effects from medication or procedure (eg, dizziness, discomfort, skin irritation, hearing loss)
- Patient adherence to treatment plan using multiple sources of information

**Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

1. Otic administration of medications: Working individually or in teams, develop a handout or short video for patients and caregivers to teach them how to administer medication into the ear of a child or an adult. Be creative in the education models used for patient education!
2. Cerumenolytics: Which one to recommend first? Working individually or in teams, research the various cerumenolytic agents available for patient use and develop a selection algorithm. The algorithm should clearly state which product (with the respective dosing regimen) would be the first to recommend to a patient, then second, and so forth.

ACUTE OTITIS EXTERNA—INTRODUCTION

Acute otitis externa (AOE) is a diffuse inflammation of the external ear canal secondary to infection.[1] The tympanic membrane or pinna may also be involved in this infectious process. AOE may occur at any age but is uncommon in children younger than 2 years.

The hallmark sign of diffuse AOE is intense tenderness of the pinna when pulled, tragus when pushed, or both, which can be inconsistent with signs observed visually, such as redness or areas of cellulitis. Diagnosis of AOE requires a rapid onset (<48 hours) of signs and symptoms of ear canal inflammation within the past 3 weeks.[1] The signs of inflammation include tenderness of the pinna, tragus, or both or diffuse canal edema, erythema, or both. Signs may also include otorrhea, regional lymphadenitis, erythema of the tympanic membrane, or cellulitis of the pinna and adjacent skin.

Symptoms of inflammation include otalgia (70%), itching (60%), or fullness (22%), with or without jaw pain or hearing loss (32%).[1] Pain best correlates with the severity of the disease.[2]

This chapter focuses on AOE, but patients sometimes present with other types of otitis externa. Chronic otitis externa is defined as otitis externa occurring for 3 months or longer. Necrotizing or malignant otitis externa is defined as the AOE infection extending to the temporal bone causing osteomyelitis. This primarily occurs in patients who are older, have diabetes mellitus, or are immunocompromised.

Epidemiology and Etiology

Patients with AOE commonly seek treatment from healthcare providers in the outpatient setting. In 2007, 2.4 million patients received a diagnosis of AOE in the ambulatory care or emergency department setting (8.1 visits per 1,000 population).[3] In ambulatory care visits in the years 2003 to 2007 for AOE, 18.6% were for children 5 to 9 years of age, 15.8% were for children 10 to 14 years of age, and 53% were for adults 20 years of age or older. One study found a peak incidence of AOE in patients 7 to 12 years of age.[4] Ambulatory care clinicians spend approximately 600,000 hours treating patients with AOE, and annual direct healthcare costs for the nonhospitalized setting in the United States are up to $500 million.[1]

① AOE is predominantly of bacterial origin (98%) in North America.[1] The primary organisms are *Pseudomonas aeruginosa* and *Staphylococcus aureus,* with a prevalence of 20% to 60% and 10% to 70%, respectively. A polymicrobial infection occurs in approximately one-third of AOE cases. A study of 173 patients with AOE in the United States from 2014 to 2016 found the most common pathogens were *P. aeruginosa* (42%), methicillin-sensitive *S. aureus* (22%), and methicillin-resistant *S. aureus* (MRSA) (8.7%).[5] This is the first study to have found higher rates of MRSA in AOE than previously reported. Other AOE pathogens found in this study were *Enterococcus faecalis* (5.2%), *Escherichia coli* (2.3%), *Stenotrophomonas maltophilia* (2.3%), *Streptococcus pneumoniae* (2.3%), coagulase-negative *Staphylococcus* species (2.3%), and *Staphylococcus epidermidis* (2.3%).[5]

AOE is seen usually in warm climates, areas of increased humidity, and patients who have increased water exposure. The most frequent diagnosis period occurs during the summer months. Genetically, patients with type A blood are more likely to be susceptible to AOE.[1] Males and females are affected equally.[4]

AOE commonly is called “swimmer’s ear,” but the etiology may be multifactorial and not associated with swimming.[1] Cerumen in the ear decreases infections, especially from *P. aeruginosa*, as it provides an acidic environment that is hostile to bacterial growth. However, this can be compromised by regular and/or aggressive cleaning of the ear, soap deposits, alkaline eardrops, or exposure to water. Local trauma to the canal, a foreign object, hearing aid use, and debris from dermatologic disorders such as atopic dermatitis may increase the risk of infection. Excessive sweating and stress could also play a role in the disease. Patients with anatomic abnormalities such as a narrow ear canal, hairy ear canal, or bone spur can be at greater risk of development of AOE.

Preserving a healthy, intact skin barrier and dry external canal are essential in preventing AOE. Using strategies to reduce moisture and decrease water accumulation in the canal can be beneficial. Drying the external ear canal with a hair dryer (on a low heat setting) after exposure to water, using earplugs or a bathing cap when swimming or engaging in water sports, and using acidifying ear drops before and after swimming and at bedtime can assist in preventing AOE.[1] Removing obstructed cerumen and avoiding local trauma to the canal are also beneficial mechanisms to prevent an infection. Objects such as cotton swabs, fingers, tweezers, or pencils should not be placed in the ear canal.[3] Healthcare providers should remove obstructed cerumen and foreign objects, not a patient or caregiver.

Patient Care Process

If a patient presents to the pharmacy or clinic with presumed AOE, it is important to assess the patient and make an appropriate referral for treatment.

Collect Information

First, gather a patient and medication history. Explicitly ask for a disease state and social history to evaluate a potential etiology as well as medication allergies. Information about specific signs and symptoms of AOE such as otalgia, itching, fullness, hearing loss, pain, tenderness, trauma, as well as duration should be obtained.

Assess the Patient

Next, assess the history provided and evaluate the physical findings. If a patient has diabetes mellitus or is immunocompromised, the patient should be referred to a physician due to a potential need for systemic therapy and an increased risk of having necrotizing otitis externa. If there is a history of radiation, systemic antimicrobials may be warranted. In the presence of a tympanostomy tube or a perforated tympanic membrane, ototoxic medications such as aminoglycosides or ones that contain alcohol or an acidifying agent should not be administered.[1] Evaluation of the patient's medical insurance, adherence to treatment, and medication preference, as well as the potential for adverse effects from medications, should occur as these factors play a role in treatment selection.

Pain also should be assessed in a patient with AOE, as it can be severe and limit activities. Assessment can occur with a numeric pain scale for adolescents and adults or faces or visual analog pain scale for children.

Plan for Treatment and Referral

② Topical antimicrobials are indicated for the treatment of AOE based on efficacy and safety data from clinical comparative studies.[1] They provide a very high concentration of the antimicrobial agent directly to the tissues, which can be 100 to 1,000 times higher than obtained with a systemic antimicrobial.

③ Topical antibiotics versus topical plus systemic antibiotics demonstrated no difference in cure rates of diffuse AOE. Using topical antibiotics alone also decreases the body's exposure to systemic antimicrobials and the likelihood of developing resistance organisms.

Topical treatment should consist of an antimicrobial agent with or without a topical steroid or low-pH antiseptic agent. Topical antimicrobials currently approved for use of AOE are listed in Table e12-1. Three meta-analyses found no meaningful difference in clinical outcomes among these types of topical therapies generally used for the treatment of AOE (drug class, use of quinolone, monotherapy versus combination therapy with or without a steroid).[1,4] The AOE guidelines do not recommend any specific medication.[1] Ciprofloxacin in a one-time dose and with a higher concentration was most recently approved for AOE treatment, but this product has not been directly compared with other agents.[7]

TABLE e12-1

Topical Treatments for Acute Otitis Externa

Generic Name	Brand Name/Generic Availability	Regimen	Additional Information
Antimicrobials			
Ciprofloxacin 0.2%	Cetraxal	0.25 mL in affected ear twice daily for 7 days	0.25 mL is a single-dose container
Ciprofloxacin 6%	Otiprio	0.2 mL in affected ear once	Administered by healthcare professional
Ofloxacin 0.3%	Generic available	6 months to <13 years: 5 drops in affected ear daily for 7 days; ≥13 years: 10 drops in affected ear daily for 7 days	
Antimicrobials with Steroid			
Ciprofloxacin 0.3% and dexamethasone 0.1%	Ciprodex	4 drops in affected ear twice daily for 7 days	
Ciprofloxacin 0.2% and hydrocortisone 1%	Cipro HC	3 drops in affected ear twice daily for 7 days	
Neomycin 0.33%, colistin 0.3%, hydrocortisone acetate 1%, and thonzonium bromide 0.05%	Cortisporin-TC	5 drops in affected ear three to four times daily for no more than 10 days	
Neomycin 3.5 mg, polymyxin B 10,000 units, hydrocortisone 10 mg/mL	Generic available	4 drops in affected ear three to four times daily for no more than 10 days	Suspension preferred
Antiseptics			
Acetic acid 2% solution	Generic available	5 drops to affected ear three to four times daily	Often used for prophylaxis
Antiseptics with Steroid			
Acetic acid 2% solution, propylene glycol diacetate 3%, and hydrocortisone 1%	Acetasol HC and generic available	5 drops to affected ear three to four times daily	

Data from References [1,2,6,7].

Some studies have found earlier symptom improvement of pain, edema, and erythema when a steroid was used in conjunction with an antimicrobial agent.[2] Adherence, adverse effects, and cost also play a role in treatment selection.

Common adverse effects of otic medications are pruritus (5%-7%) and local reactions (4%-5%).[1] Hypersensitivity to aminoglycosides, especially neomycin, can occur in up to 15% of patients.[2] "Home remedies"—such as isopropyl alcohol or acetic acid mixed with isopropyl alcohol or water—have not have been evaluated in clinical trials. Acetic acid may be used topically after water exposure as a prophylactic acidifying agent but has not been studied.[2] Ear candling should not be used for AOE and may cause harm.[1]

Systemic antimicrobials are not indicted for diffuse, uncomplicated AOE. Patients with a specific patient history as previously discussed or expansion of the infection outside of the ear canal would warrant consideration of systemic therapy.[1] Systemic therapy may also be considered if there is concern that topical therapy would not reach the area of infection. However, it is recommended that a clinician insert a wick or perform aural toilet or both, if the canal is obstructed, and then follow that with topical therapy.

④Nonprescription pain medications such as acetaminophen or a nonsteroidal anti-inflammatory drug (NSAID), such as ibuprofen, may be recommended for pain if the patient does not have a contraindication to use. NSAIDs could decrease the inflammation process of AOE. An opioid may be considered in conjunction with a nonprescription medication based on the severity of pain. Oral administration of pain medication is the preferred route of treatment.[1] Topical anesthetic eardrops are not indicated for AOE and can mask disease progression. Nonpharmacologic pain treatments such as cold or heat compresses and distraction or relaxation techniques have not been found to be beneficial for AOE.

Implement by Making Recommendations to the Patient

⑤It is important to provide appropriate education on administering otic medications to parents and caregivers. Self-administration of otic drops is challenging. It is best to have someone else administer eardrops. Topical otic drops should be placed in the ear canal (affected ear upward) with the patient lying down on their side. The patient or caregiver may gently move the pinna back and forth or “pump” the tragus to ensure the canal fills with the medication and trapped air is released. The patient should remain lying down for 3 to 5 minutes. If a wick is placed, it is important not to remove it until it falls out on its own.

To decrease the possibility of trauma, patients should not try to manipulate the ear or insert anything into the ear.[1] Patients should be encouraged to avoid water activities for 7 to 10 days while being treated. Patients with hearing aids should limit use until symptoms have improved. Earplugs or cotton balls with petroleum jelly may be used to decrease water entering the canal during showering, bathing, or washing of the hair.

Follow-up by Monitoring and Evaluating Outcomes

Explain to the patient that once treatment is started, improvement in signs and symptoms (eg, otalgia, itching, fullness, pain, tenderness) usually occurs within 48 to 72 hours. However, symptoms resolution may take up to 2 weeks. If there is no improvement within the expected period, the patient should seek reassessment by the clinician. The patient should complete the prescribed therapy even if symptoms improve. Lastly, counsel on strategies to reduce moisture and decrease water accumulation in the external ear canal after the infection clears.

Conclusion

AOE is a common ear infection treated with topical therapy consisting of an antimicrobial agent with or without a steroid. Pain also should be assessed and patients should be treated with nonprescription or prescription medications. Patients with AOE should be referred to a clinician for treatment. Pharmacists can assist with patient histories, treatment recommendations, and counseling patients on the appropriate administration of otic medications.

CERUMEN IMPACTION

⑥The production of cerumen or earwax is a naturally occurring process of the body. Its purpose is to protect, clean, and lubricate the external ear canal.[8] Cerumen is a mixture of secretions from the ear canal and sloughed epithelial cells.

⑦An accumulation of cerumen can physically occlude (partially or fully) the canal and result in patient symptoms and/or an obstructive view of the ear canal, tympanic membrane, or audiovestibular system during an assessment. This is cerumen impaction. Symptoms of impaction include otalgia, fullness, itching, tinnitus, discharge, odor, cough, vertigo, and hearing loss. Diagnosis is formally made upon physical examination with an otoscope.

Epidemiology and Etiology

In the United States, approximately 12 million patients are seen for issues with cerumen and subsequently, 8 million removal procedures are performed.[8] Cerumen impaction occurs in 10% of children and 5% of adults. More than one-third of developmentally delayed patients and older adults have impaction issues, which are often underdiagnosed. Young children may not be able to verbally described symptoms. Studies estimate that cerumen impaction occurs in 19% to 65% of patients older than 65 years of age. In 2012, Medicare spent almost $50 million on cerumen-related procedures. Patients with hearing aids or dermatological conditions may be at risk for an increased incidence of cerumen impaction.[9]

Patients at a higher risk for impaction should be educated on preventive measures. Patients with hearing aids should have regularly scheduled ear examinations with a physician or audiologist and perform home cleaning as appropriate. Patients should remove the hearing aid for 8 hours each day to decrease cerumen accumulation.[10]

⑧ Pharmacists should educate patients on appropriate ear hygiene. The outer ear can be cleaned with soap and water while showering or taking a bath. Excessive cleaning of the ears can result in impaction, irritation, or infection. Cerumenolytic agents may be used prophylactically. Self-irrigation devices may be used to prevent cerumen accumulation. Objects such as cotton swabs or foreign objects should not be placed in the ear canal to facilitate cleaning. These objects can worsen cerumen impaction and cause local trauma to the skin or tympanic membrane. Ear candles are not recommended for use by the Food and Drug Administration and may cause ear trauma.[11]

Anatomy and Mechanisms of Disease

Cerumen is a combination of secretions from sebaceous and ceruminous glands of the outer two-thirds of the ear canal and sloughed off epithelial cells.[8,10] Cerumen is removed from the ear canal in a natural self-cleaning process, which is aided by the movement of the jaw. When the self-cleaning process fails, cerumen can accumulate and cause symptoms of impaction. Some patients also produce excessive cerumen. Cerumen that is not blocking the canal view or causing symptoms should not be altered. Cerumen should be removed before auditory tests, but its presence does not affect ear thermometer measurements.[9]

Patient Care Process

If a patient presents to the pharmacy or clinic with cerumen impaction, it is important to assess the patient and make an appropriate referral for treatment, if indicated.

Collect Information

First, gather a patient's medication history. Explicitly ask about the patient’s disease states and medications to determine if self-care is an option. Symptoms of cerumen impaction should be elicited.

Assess the Patient

Patients should be referred for care when they have an immunocompromising condition, diabetes mellitus, renal failure, ear canal anatomic abnormalities, past radiation to the head or neck, tympanostomy tubes, or a perforated tympanic membrane. Patients with diabetes mellitus have a higher pH in the cerumen and infections may occur more frequently.[10] Patients with past radiation may have harder, drier cerumen.[8] Nonverbal or cognitively impaired patients should be referred to a physician for a physical ear exam and determination of diagnosis and treatment. Patients on anticoagulant therapy or who have a disease affecting coagulation or bleeding are at a higher risk of bleeding from certain treatments.

Patients who are asymptomatic and whose ear canal can be visualized upon otoscopy do not require treatment.

Plan for Treatment and Referral

If cerumen impaction is likely, there are four treatment options, of which a combination may be used. Options include observation, the use of cerumenolytic agents, irrigation, and/or manual removal.[8] Clinical evidence does not find one treatment option superior to another. Irrigation and manual removal results in immediate symptom resolution. Cerumenolytics may take a few days to effect removal; these agents are useful for prophylaxis.

Treatments should be selected based on patient resources and potential ease of removal. The goal of treatment is to alleviate the patient’s symptoms.

Observation

As cerumen is removed naturally from the ear, over time there can be a spontaneous resolution of symptoms; thus, observation is an option for treatment. However, symptoms can worsen and complete obstruction of the canal can occur.

Cerumenolytics

⑨Cerumenolytics are agents that soften cerumen. They may reduce the need for irrigation or manual removal, or they may be used in combination with these treatments.

The three types of cerumenolytics include (1) water-based agents, (2) oil-based agents, and (3) nonwater, nonoil-based agents. Water-based agents induce hydration, thus fragmenting the corneocytes within the cerumen.[8] Examples include acetic acid, docusate sodium, hydrogen peroxide, saline, water, sodium bicarbonate, and triethanolamine polypeptide oleate-condesate.[8,9] Oil-based agents lubricate and soften but do not disintegrate cerumen.[8] Examples include almond, atachis, and mineral oil. Olive oil should not be used due to lack of efficacy.[9] Nonwater, nonoil-based agents mechanisms have not been fully elicited in studies. Examples include carbamide peroxide and choline salicylate/glycerine.

A 2018 Cochrane review found no advantage for any one type of cerumenolytic agent and that an active ingredient was no better than saline or water.[12] Water-based and oil-based treatments did not differ in efficacy. Dosing regimens of cerumenolytics vary, but in general, multiple drops are instilled in the ear canal once or twice daily for several days.[9,10] Benefits of these agents are that the patient or caregiver can administer them at home.

Cerumenolytics are not recommended for children younger than 3 years of age or patients with tympanostomy tubes or a perforated tympanic membrane.[8] Complications of using cerumenolytic agents include dizziness, discomfort, skin irritation, and transient hearing loss.

Irrigation

Aural irrigation flushes out cerumen from the ear canal through the use of water and a syringe or irrigator. Water should be at body-temperature and injected gently to avoid trauma.[9] A 50/50 mixture of hydrogen peroxide and water may also be used.[10] Oral jet irrigators should not be used in the ear due to their high pressure and potential ear trauma.[8] However, some devices have modified tips for aural use.

Pretreatment with a cerumenolytic agent may soften wax and facilitate removal by irrigation. Young children may not cooperate with irrigation of the ear canal. Irrigation should not be performed in patients with anatomic abnormalities of the ear, tympanostomy tubes, a perforated tympanic membrane or past ear surgery. Complications of treating cerumen impaction with irrigation include temporary dizziness, pain, trauma to the skin, or tympanic membrane perforation.[8]

Manual Removal

⑩Manual removal of cerumen is accomplished in medical settings using ear probes, hooks, spoons, forceps, or curettes; suction devices may also be used.

Patients and caregivers should not attempt to remove cerumen using objects found in the home. It is best to have an expert or clinician remove cerumen manually. Even an expert may have a difficult time manually removing cerumen from young children.

A benefit of manual removal is that moisture is not introduced to the ear, thus decreasing potential infection.[8,10] Manual removal is usually used in patients with anatomical abnormalities, a history of ear surgery, immunocompromised disease states, diabetes mellitus, tympanostomy tubes, or a perforated tympanic membrane. Complications of using manual removal with a device include laceration of the ear canal, discomfort, bleeding, infection, tinnitus, or hearing loss.[8] Manual removal should be used with caution in patients who are taking anticoagulants or have a disease state that increases bleeding.

Implement by Making Recommendations to the Patient

A patient should be appropriately counseled on how to use a cerumenolytic agent and self-irrigation device. To prevent vertigo, eardrops should be at body temperature when administering them to the patient.[9]

Follow-up by Monitoring and Evaluating Outcomes

Cerumen impaction is resolved when the patient's symptoms resolve or the clinician can visualize the ear canal upon inspection. Patients experiencing hearing loss with cerumen impaction may regain hearing once the impaction is treated. Patients experiencing symptoms after impaction removal should be referred. Pharmacists may also educate patients on preventive measures of impaction.

Conclusion

Cerumen is a natural product of the body, serving as a protectant, emollient, and bactericidal agent of the ear canal. Cerumen should be left alone if patients are asymptomatic and the ear canal can be visualized during otoscopy. If symptoms of impaction occur or the canal is not visualized, several treatment options exist. Appropriately identifying patients who should be referred for care is essential. Home treatment and prophylactic agents available at the pharmacy can be recommended as self-care for many patients.

SELF-ASSESSMENT QUESTIONS

1. Acute otitis externa is an infection affecting the:

A. Tympanic membrane

B. External ear canal

C. Pinna

D. Osseous labyrinth

2. Which sign or symptom best correlates with the severity of an AOE infection?

A. Erythema

B. Edema

C. Otalgia

D. Itching

3. Which of the following patient factors is more likely to increase the incidence of AOE?

A. Male

B. Gardening

C. Type O blood

D. Living in Florida

4. Which of the following is a primary organism responsible for AOE?

A. *Streptococcus pyogenes*

B. *Staphylococcus aureus*

C. *Klebsiella pneumoniae*

D. *Escherichia coli* (*E. coli*)

5. Which of the following is a preventive strategy for AOE?

A. Use a cotton swab in the ear canal after showering

B. Use a hairdryer on high setting after bathing to dry the canal

C. Use earplugs when swimming or participating in water sports

D. Use tweezers to remove cerumen in the external canal

6. PK is a 43-year-old woman diagnosed with AOE. She has hypertension and currently takes lisinopril daily. She has no other medical conditions or medications. The physician in clinic asks for your recommendation of a topical treatment plan. Which of the following is the best treatment plan for PK?

A. Ciprofloxacin 6%.

B. Acetic acid 2% solution.

C. Ciprofloxacin 0.3% and dexamethasone 0.1%.

D. Neomycin 3.5 mg, polymyxin B 10,000 units, hydrocortisone 10 mg/mL.

E. All of the above are appropriate treatment options.

7. DJ is a 54-year-old man diagnosed with AOE. He has a perforated tympanic membrane from diving and hyperlipidemia for which he takes rosuvastatin. The physician in clinic asks for your recommendation of a topical treatment plan. Which of the following is the best treatment plan for DJ?

A. Ofloxacin 0.3%.

B. Acetic acid 2% solution.

C. Acetic acid 2% solution, propylene glycol diacetate 3%, and hydrocortisone 1%.

D. Neomycin 0.33%, colistin 0.3%, hydrocortisone acetate 1%, and thonzonium bromide 0.05%.

E. All of the above are appropriate treatment options.

8. CW is a 5-year-old girl diagnosed with AOE. She has no medical conditions or current medications. The physician in clinic asks for your recommendation of a topical treatment plan. Which of the following is the best treatment plan for CW?

A. Ciprofloxacin 0.2% and hydrocortisone 1%.

B. Neomycin 3.5 mg, polymyxin B 10,000 units, hydrocortisone 10 mg/mL.

C. Acetic acid 2% solution, propylene glycol diacetate 3%, and hydrocortisone 1%.

D. Alternatives A, B, and C are all correct.

E. None of the above; children should receive systemic antibiotics for AOE.

9. Which of the following patients should be considered for systemic antibiotics if they are diagnosed with AOE?

A. A 75-year-old with diabetes mellitus

B. A 34-year-old professional swimmer

C. A 12-year-old with rhinosinusitis

D. A 4-year-old with tympanostomy tubes

10. Which of the following actions is correct when educating a caregiver to administer eardrops to a patient?

A. Have the patient lie on their back

B. Remove the wick to insert the medication

C. “Pump” the tragus to release air from the canal

D. Remain lying down for 1 to 2 minutes after drops are instilled

11. Which of the following is a symptom of cerumen impaction?

A. Itching

B. Odor

C. Fullness

D. Tinnitus

E. All of the above

12. Which of the following should NOT be used for the treatment of cerumen impaction?

A. Cerumenolytic agents

B. Ear candles

C. Irrigation

D. Manual removal

13. Which of the following patients can be treated with self-care measures for cerumen impaction?

A. A 15-year-old with a perforated tympanic membrane

B. A 32-year-old who is pregnant

C. A 58-year-old with a history of neck radiation

D. A 73-year-old with severe dementia

14. Which of the following statements is TRUE regarding cerumenolytics?

A. Oil-based agents are preferred to water-based agents.

B. Water-based agents are preferred to oil-based agents.

C. Nonwater, nonoil-based agents are preferred to water- and oil-based agents.

D. No type of cerumenolytic agents has been found to be better than another.

15. Which of the following is a potential adverse effect of using a cerumenolytic agent?

A. Dizziness

B. Bleeding

C. Fever

D. Dysgeusia

SELF-ASSESSMENT QUESTION-ANSWERS

1. **B**. Acute otitis externa is a diffuse inflammation of the external ear canal. The pinna or tympanic membrane may be involved, but inflammation of the external canal is required for diagnosis.

2. **C**. Otalgia or pain best correlates with the severity of the disease.

3. **D**. AOE is more predominately diagnosed in patients who live in warm, humid climates, such as Florida.

4. **B**. *Staphylococcus aureus* and *Pseudomonas aeruginosa* are the two primary organisms causing AOE.

5. **C**. Using earplugs or a bathing cap during swimming or water sports can decrease exposure to water and moisture, thus decreasing AOE.

6. **E**. All of the topical treatment options listed are appropriate for PK. She has no underlying disease states or medication concerns to influence treatment recommendations. The AOE guidelines do not recommend one treatment option over another based on clinical evidence.

7. **A**. Since DJ has a perforated tympanic membrane, ototoxic medications, alcohol-based, and acidifying agents should not be used for AOE treatment. Quinolone eardrops may be used.

8. **D**. All three topical treatment options are correct for CW. Children may receive topical treatment for AOE.

9. **A**. A patient with diabetes mellitus should be evaluated for the need of systemic antibiotics in addition to topical treatment for AOE because the disease can impair host defenses.

10. **C**. Topical otic drops should be placed in the ear canal (affected ear upward) with the patient lying down on their side. The caregiver may gently move the pinna back and forth or “pump” the tragus to ensure the canal fills with the medication and trapped air is released. The patient should remain lying down for 3 to 5 minutes. If a wick is placed, it is important not to remove it.

11. **E**. Symptoms of impaction include otalgia, fullness, itching, tinnitus, discharge, odor, cough, vertigo, and hearing loss.

12. **B**. Ear candles should not be used for the treatment of cerumen impaction due to the risk of trauma.

13. **B**. Pregnancy is not a contraindication to home treatment for cerumen impaction. Patients with an immunocompromised state, diabetes mellitus, renal failure, ear canal anatomic abnormalities, past radiation to the head or neck, cognitive impairment such as dementia, tympanostomy tubes, or a perforated tympanic membrane should be referred for care.

14. **D**. A 2018 Cochrane review did not find that one type of cerumenolytic agent was better than another.

15. **A**. Potential adverse effects of cerumenolytic agents include dizziness, discomfort, skin irritation, and transient hearing loss.

Chapter e13: Nonspecific Respiratory Tract Symptoms (with Cough)

Brandon James Sucher

KEY CONCEPTS

KEY CONCEPTS

① Cough is classified as acute, subacute, or chronic based on duration of symptoms.

② Cough is an essential component for lung health maintenance, but persistent or excessive cough ceases to be protective, is bothersome, and adversely affects quality of life.

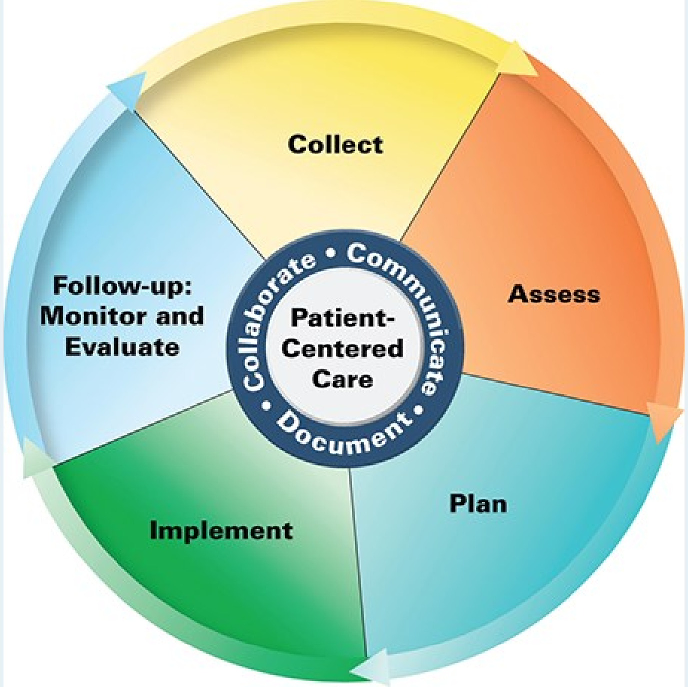
③ Although cough is associated with a variety of diseases, the duration of cough helps narrow the potential etiologies for cough symptoms.

④ The presence of dyspnea, red flag symptoms, and/or symptoms suggestive of acute bacterial rhinosinusitis indicates the need for referral to the patient’s primary care physician.

⑤ Treatment trials (eg, intranasal corticosteroids, first-generation antihistamines, treatments for gastroesophageal reflux disease) can help rule out common causes of chronic cough.

PATIENT CARE PROCESS

Patient Care Process for Cough



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Duration of symptoms, red flag symptoms (see Table e13-5), and the presence and severity of symptoms associated with acute bacterial rhinosinusitis (see Tables e12-6 and e12-7)
- Use validated symptom questionnaires as needed (see text).
- Current medical conditions, family history, and occupational and environmental (eg, pets, carpet/bedding, mold) history
- Tobacco and marijuana use, prior allergies, and immunization history and medications
- Ability to access medications and adherence to current medications

Assess

- Indicators of acute, subacute, or chronic cough (see Table e13-1 and text)
- Red flag symptoms (see Table e13-5) or symptoms associated with acute bacterial rhinosinusitis (see Tables e12-6 and e12-7) indicating need for referral to primary care provider
- Active medical problems associated with chronic cough (see Table e13-2)
- Possibility of cough related to gastroesophageal reflux disease (GERD; see Chapter 50, "Gastroesophageal Reflux Disease")
- If applicable, estimate creatinine clearance to assess dosing of current or new medications.
- If the patient taking any medications associated with cough (especially ACE inhibitors; see Table e13-4)

Plan*

- Refer to primary care provider for assessment of cough with dyspnea, red flag symptoms (see Table e13-5), or symptoms related to environmental or occupational exposures.
- Smoking cessation interventions in those ready to quit smoking (see Chapter 85, "Substance Use Disorders I: Opioids, Cannabis, and

Stimulants")

- Immunizations if not contraindicated (eg, influenza, pneumococcal, diphtheria, tetanus, acellular pertussis; see Chapter 147, "Vaccines, Toxoids, and Other Immunobiologics")
- Step-up therapy in patients with asthma-related cough to improve symptom control (see Chapter 44, "Asthma")

Implement[*]

- Patient education
- Recommendations that are within scope of practice
- Document in health record
- Instructions and schedule for follow-up

Follow-up: Monitor and Evaluate

- Reevaluate in 4 to 6 weeks and reassess using validated symptom questionnaires as needed.
- Adherence to care plan
- Adverse drug effects
- Immunizations for those deferred earlier (see Chapter 147)
- For acute or subacute cough that persists for more than 8 weeks (ie, progresses to chronic cough), trial of an oral first-generation antihistamine and/or intranasal corticosteroid
- For chronic cough that does not improve with an oral first-generation antihistamine and an intranasal corticosteroid, refer patient to primary care provider for ruling out asthma and nonasthmatic eosinophilic bronchitis before recommending treatment trial for GERD.
- For GERD-induced cough, improvement in cough may take up to 3 months, even though GERD symptoms may improve within 4 to 8 weeks.
- For ACE-inhibitor–induced cough, cough usually subsides within 8 weeks of discontinuing the medication but may take up to 1 year.

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Create a flow chart that outlines the sequence of therapeutic approaches for the four most common causes of chronic cough. Indicate the name of the medication class that may be used for a therapeutic trial when available as an over-the-counter medication. When a therapeutic trial of an over-the-counter medication is not appropriate, indicate referral to the patient's primary care physician for each of the respective causes of chronic cough.

This activity provides an opportunity for students to practice applying the assess, plan, and implement steps of the patient care process.

INTRODUCTION

①②①② Cough is the second most common symptom patients report as the reason for seeking healthcare in ambulatory settings.[1] In addition to occurring as a common symptom associated with respiratory diseases, cough serves as a protective respiratory reflex and also can be initiated voluntarily.[2] Cough is classified as acute, subacute, or chronic based on duration of symptoms (Table e13-1).[3] As a defense mechanism, cough protects the airways from aspiration of foreign substances, expels infectious organisms and harmful environmental insults, and clears excessive mucus secretions[2,4]However, when cough is excessive or persists, it can be detrimental to patients through adverse consequences such as syncope, urinary incontinence, vomiting, chest pain, rib fractures, sleep disturbances, relationship difficulties, social embarrassment, and depression.[5,6] An increased frequency of cough also adversely affects health-related quality of life.[5]

TABLE e13-1

Classification and Duration of Cough Symptoms

Classifications	Duration (weeks)
Acute	<3
Subacute	3-8
Chronic	>8

Data from Reference 3.

EPIDEMIOLOGY AND ETIOLOGY

The estimated prevalence of chronic cough varies and depends on the epidemiological study design, duration of symptoms used to define chronic cough, and how the data is obtained (eg, diagnosis codes, patient report, physician diagnosis).[7,8] The global prevalence of chronic cough is approximately 10% and the prevalence of chronic cough in the United States ranges between 10% and 15%.[8] Chronic cough is more common in women and more commonly occurs in patients aged 50 to 70 years old.[7,9] Chronic cough is more common in patients who continue to smoke, which may reflect a protective response to inhaled irritants rather than hypersensitive cough.[10] Results from the ACHOO study revealed the burden associated with acute cough and/or cold symptoms. Fifty-two percent of the survey respondents indicated that their daily lives were affected “a fair amount” or “a lot” when they had a cough and/or cold. Participants also reported a decrease of 26% in their perceived productivity when they were experiencing cough and/or cold symptoms, and 45% of respondents reported missing at least 1 day of work or school.[5]

The etiology of cough may occur anywhere within the realm of the vagus nerve, which is the longest nerve of the autonomic nervous system. Therefore, cough may arise from a variety of systems (eg, respiratory, cardiovascular, gastrointestinal).[4] Viral upper respiratory tract infections are the most common cause of acute cough, followed by exacerbations of underlying diseases (eg, asthma, chronic obstructive pulmonary disease [COPD], upper airway cough syndrome [UACS], bronchiectasis) and pneumonia.[2,3] The most common cause of subacute cough is postinfectious cough followed by exacerbations of underlying diseases.[2,4,8] Asthma (including cough-variant asthma), UACS, nonasthmatic eosinophilic bronchitis (NAEB), and GERD are the most common causes of chronic cough in adult nonsmokers with UACS being the most common cause of chronic cough in the United States.[3,11] Additional causes of chronic cough are included in Table e13-2.[3,12]

TABLE e13-2

Causes of Chronic Cough

Common	Less Common	Rare
• Upper airway cough syndrome • Asthma (including cough variant asthma) • Nonasthmatic eosinophilic bronchitis • Gastroesophageal reflux disease	• Medications (especially ACE inhibitors) • Occupational and environmental exposure (especially cigarette smoking) • Chronic obstructive pulmonary disease • Bronchiectasis • Bronchiolitis • Obstructive sleep apnea • Lung cancer • Left ventricular heart failure • Somatic cough syndrome • Tic cough	• Aortic aneurysm • Pulmonary embolism • Aspiration of food and liquids due to oral-pharyngeal dysphagia • *Bordetella pertussis* • Interstitial lung disease (eg, sarcoidosis) • Tuberculosis • Enlarged tonsils • Basidiomycetes fungi • Cervical spondylosis • Heterotopic salivary gland at the base of the tongue • Idiopathic pulmonary fibrosis • External ear disease

Data from References 3,6,13–15.

ANATOMY AND MECHANISMS OF DISEASE

Physiology of Cough

Cough is a host defense mechanism. The cough reflex prevents introduction of particulate matter in the lower airways. The respiratory epithelial cells are covered with beating cilia and mucus. The beating cilia propel the overlying mucous layer upward toward the larynx. When mucociliary clearance is impaired due to damage of cilia (eg, smoking), coughing serves as a compensatory mechanism to help clear aspirated material, excess secretions, and foreign bodies.[16]

The mechanism of a cough is described as the following sequence: (1) inspiration; (2) forced expiration against a briefly closed glottis, which builds intrathoracic pressure; and (3) opening of the glottis with a subsequent rapid expulsion of air.[17,18] Turbulent airflow through the trachea, larynx, and vocal cords during expiration results in the sound of a cough.[2] Physiologically, cough can be described as laryngeal or tracheobronchial. Laryngeal cough is a true reflex stimulated by aspiration of foreign material, and the amount of inspiration may be minimal. Tracheobronchial cough can be initiated voluntarily and occurs distal to the larynx.[18]

A simplified overview of the cough pathway can be described via the following compartments: (1) the afferent arm (from the cough receptors to the respiratory center); (2) the respiratory center; and (3) the efferent arm (from the respiratory center to the respiratory muscles and larynx).[18]

In the afferent arm, cough receptors in the airways are located in the mucosa and submucosa.[14] Cough receptors are differentiated into three groups: (1) rapidly adapting receptors (RARs); (2) slowly adapting receptors (SARs); and (3) C-fiber nociceptors.[19] These cough receptors are located throughout the airways and lung parenchyma and are activated by a variety of triggers (Table e13-3).[20] Both RARs and SARs are considered pulmonary stretch receptors, which regulate the inspiratory and expiratory phases of coughing. Rapidly adapting receptors are relatively insensitive to chemical stimulation, but they are sensitive to mechanical stimulation. Slowly adapting receptors are also believed to be responsible for the inflation reflex, which terminates inspiration and initiates expiration after the lungs are adequately inflated. C-fiber nociceptors are relatively insensitive to mechanical stimulation, but they are sensitive to bradykinin, capsaicin, ozone, nicotine, prostaglandin E2, and other inflammatory mediators and environmental stimulants.[17,19] Cough receptors have voltage-gated ion channels such as the transient receptor potential vanilloid-1 (TRPV-1) and transient receptor potential ankyrin-1 (TRPA-1), which are found on RARs and C-fiber receptors.[4,17] Cough sensitivity depends on the location of the stimulation and the type of stimulation. For example, the larynx and proximal large airways are more mechanosensitive and less chemosensitive, whereas the peripheral airways are more chemosensitive and less mechanosensitive.[11,19]

Data from Reference 20.

Cough sensory input travels from cough receptors to the respiratory center via the vagus nerve. The respiratory center consists of the nucleus tractus solitaris (NTS) and the cortex.[18] Vagal afferent fibers enter the brainstem via the NTS for central processing of afferent input and regulation of cough. The brainstem then controls the duration and intensity of cough. Through cortical processing, patients can sense an irritation or itch in the airways. Then patients can consciously control a cough behavior to satisfy the urge to cough.[19] In summary, the NTS is responsible for a reflex cough, and the cortex is responsible for voluntarily initiating or voluntarily inhibiting a behavioral cough.[18,19]

The efferent arm interacts with the larynx, respiratory muscles, and pelvic sphincters. The larynx and respiratory muscles are responsible for the previously described three phases of the cough mechanism. The activation of pelvic sphincters during a cough helps prevent incontinence during a cough.[18]

Pathophysiology Associated with Increased Cough

Acute and Subacute Cough

Viral Infections

In the acute phase, respiratory viruses cause changes in the function of the epithelial cells, which initiates an immune response. The immune response includes eosinophils, neutrophils, lymphocytes, and cytokines[19] Eosinophils increase sensory nerve responsiveness and release proteins that stimulate C-fiber nociceptors. The inflammatory response from neutrophils can sensitize peripheral airway nerves and stimulate the cough reflex. Lymphocytes release cytokines that also enhance eosinophilic and neutrophilic inflammation Additionally, respiratory viruses also cause a decrease in expression of M2 muscarinic receptors, which normally decrease cough sensitivity.[21] Collectively, these changes increase cough receptor sensitivity even after the respiratory virus is cleared. This helps explain persistent cough and cough hypersensitivity in the subacute phase.[19]

Chronic Cough

Patients with chronic cough may also experience cough hypersensitivity. Cough hypersensitivity syndrome is characterized by troublesome coughing often triggered by low levels of thermal, mechanical, or chemical exposure.[20,18] New onset or exacerbations of asthma or COPD are potential causes of chronic cough (see Chapter 44, “Asthma” and Chapter 45, “Chronic Obstructive Pulmonary Disease”).

Upper Airway Cough Syndrome

Upper airway cough syndrome (previously known as postnasal drip syndrome) is a cough reflex related to inflammatory conditions of the nose and sinuses. The pathophysiology of UACS is not well understood. Direct irritation of nasal mucosa and/or mechano- or chemostimulation from a postnasal drip may initiate a cough. Alternatively, airway inflammation of the upper and/or lower airways may increase the sensitivity of the airway nerves, ultimately resulting in enhanced cough responsiveness such that innocuous stimuli promote coughing.[11,19]

Gastroesophageal Reflux Disease

Due to impaired function of the lower esophageal sphincter, acid and other gastric contents move from the stomach to the distal esophagus. In addition to heartburn and regurgitation, patients may also experience cough. After treatment with proton pump inhibitors, some patients may continue to experience cough.[22] This suggests other substances such as bile, pepsin, and other gastric enzymes may induce cough. Patients with GERD and chronic cough also have elevated levels of substance P, which inhibits apoptosis, increases migration, and prolongs the survival of eosinophils.[21]

Smoking

Tobacco smoke is cytotoxic to the ciliated respiratory epithelial cells. Smoking also decreases cough sensitivity. However, cough sensitivity recovers within 2 weeks after smoking cessation.[23] This helps explain why some patients complain of an increase in cough after smoking cessation. Although the frequency of smoking marijuana is significantly less compared to smoking tobacco, the airway inflammation induced by smoking marijuana is similar to smoking tobacco.[23]

Occupational and Environmental Exposure

Patients may be exposed to respiratory irritants such as vapors, gases, dusts, and fumes in their occupations. Additional environmental exposures include emissions from biomass fuel, wood stoves for cooking or heating, air pollution, cleaning products, natural and manmade disasters (eg, volcano ash, wildfires, World Trade Center collapse), and hobbies (eg, glue for making models, paints, home improvement projects).[23]

Medications

Angiotensin-converting-enzyme (ACE) inhibitors are the most likely medications to cause a cough in patients with approximately 20% of patients taking ACE inhibitors complaining of cough.[15] ACE inhibitor–induced cough is thought to be caused by elevations in bradykinin, substance P, and/or prostaglandins. In addition to converting angiotensin I to angiotensin II, ACE catalyzes the breakdown of bradykinin and substance P. Inhalation of bradykinin stimulates a cough, and substance P is a neuropeptide that is released upon stimulation of C-fibers. Since ACE inhibitor–induced cough has been successfully treated with nonsteroidal anti-inflammatory drugs (NSAIDs), prostaglandins may also play a role in the pathogenesis of ACE inhibitor–induced cough.[21] Onset of cough varies among patients and can occur as early as within a few hours of taking an ACE inhibitor to as long as months. After discontinuing the ACE inhibitor, improvement in cough symptoms occurs within days to weeks; however, complete resolution of cough symptoms may take up to three months.[24] If additional treatment to mitigate cough is needed after discontinuing the ACE inhibitor, NSAIDs, theophylline, dihydropyridine calcium channel blockers, ferrous sulfate, or inhaled cromolyn may be considered.[25]

Excipients in inhaled medications may trigger a cough in some patients with asthma or COPD. Changing the inhaler device or using a spacer may help decrease cough for these patients. Some patients may require a 1- to 2-week treatment with oral corticosteroids to mitigate cough hypersensitivity.[22] Table e13-4 includes some additional examples of medications associated with respiratory adverse effects. It is important to note that this is not a comprehensive list (also see Chapter e48, “Drug-Induced Pulmonary Diseases”).

TABLE e13-4

Medications Associated with Respiratory Symptoms

	Cough	Dyspnea	Incidence	Mechanism	Treatment (in addition to discontinuing offending medication)
ACE inhibitors	X	X	• 5%-30% (cough) • 4.5% (dyspnea)	Elevations in bradykinin and substance P and/or enhanced acetylcholine-induced contraction of bronchial smooth muscle	NSAIDs, theophylline, dihydropyridine calcium channel blockers, ferrous sulfate, or inhaled cromolyn
Beta blockers		X	0.5%-5.3%	Blockade of beta-2 receptors in bronchial smooth muscle	• Inhaled beta-2 agonists • Use of cardioselective beta blockers when indicated
Amiodarone	X	X	4%-6%	Influx of inflammatory or immune effector cells to the lung and/or lung parenchymal cell injury with subsequent fibrosis	Corticosteroids
Aspirin and NSAIDs		X	4%-25%	Increased leukotrienes and/or increased sensitivity to leukotrienes	Inhaled beta-2 agonists
Sitagliptin	X		5%-6%	Disruption of neuropeptides and/or cytokines that rely on DPP IV for activation or inactivation	Intranasal or inhaled corticosteroids
Inhaled insulin	X	X	26%-29%	Unknown	None known
Opioids	X	X	28%-66%	Activation of the vagus nerve via inhibition of sympathetic outflow, enhance RARs via release of histamine, and/or constriction of tracheal and bronchial smooth muscle	Corticosteroids, dextromethorphan, magnesium sulfate, lidocaine, propofol
Bleomycin	X	X	10%	Fibrosis of alveolar septa and enlargement of the type II alveolar lining cells	Corticosteroids
Methotrexate	X	X	2%-3%	Pleural pulmonary fibrosis	None known
Bromocriptine	X	X	8%-14%	Pleural pulmonary fibrosis	None known
Cholinesterase inhibitors	X	X	1%	Unknown	None known

Data from References 24–27.

PATIENT CARE PROCESS

Collect Information

- How long has the patient experienced a cough?
- Inquire about the presence of red flag symptoms (Table e13-5).
- Inquire about the presence and severity of symptoms associated with acute bacterial rhinosinusitis (Tables e12-6 and e12-7).
- For adults and adolescent patients (>14 years of age), the patient may complete either of the recommended validated cough questionnaires [ie, Cough Quality-of-Life Questionnaire (CQLQ) or Leicester Cough Questionnaire (LCQ)]. For children less than 14 years of age, the parent may complete the Parent Cough-Specific Quality-of-Life Questionnaire (PC-QOL).
- Obtain an active medical problem list.
- Obtain a family history.
- Obtain an occupational and environmental (eg, pets, carpet/bedding, mold) history.
- Ask about tobacco and marijuana use.
- Inquire about history of allergies and adverse effects.
- Obtain immunization history.
- Obtain and document a complete medication list (ie, name, indication, strength, formulation, and dosing schedule of all prescription, nonprescription, and complementary medications).
- Inquire about the patient's ability to access medications with respect to ability to afford medications as well as ability to pick up medications.
- Inquire about the patient's adherence to their current medications.

TABLE e13-5

Red Flag Symptoms with Report of Nonspecific Cough or Other Respiratory Symptoms

- Hemoptysis
- Smoker >45 years of age with a new cough, change in cough, or coexisting voice disturbance
- Adults aged 55-80 years who have a 30 pack-year smoking history and currently smoke or who have quit within the past 15 years
- Prominent dyspnea, especially at rest or at night
- Hoarseness
- Systemic symptoms (ie, fever, weight loss, peripheral edema with weight gain)
- Trouble swallowing when eating or drinking
- Vomiting
- Recurrent pneumonia
- Abnormal respiratory exam and/or abnormal chest radiograph coinciding with duration of cough

Data from Reference 3.

TABLE e13-6

Criteria for the Diagnosis of Sinusitis

Major symptoms	• Purulent anterior nasal discharge • Purulent or discolored posterior nasal discharge • Nasal congestion or obstruction • Facial congestion or fullness • Facial pain or pressure • Hyposmia or anosmia • Fever (for acute sinusitis only)
Minor symptoms	• Headache • Ear pain, pressure, or fullness • Halitosis • Dental pain • Cough • Fever (for subacute or chronic sinusitis) • Fatigue

Note: Presence of at least two major symptoms or one major symptom in combination with at least two minor symptoms is the diagnostic criteria for sinusitis.

Data from Reference 29.

TABLE e13-7

Clinical Presentations Indicating Acute Bacterial Rhinosinusitis

Symptom Type	Symptom Characteristics
Persistent symptoms	• Symptoms lasting >10 days without improving
Severe symptoms at onset	• High fever [>102°F (38.9°C)] • Purulent nasal discharge or facial pain lasting at least three consecutive days
Worsening symptoms	• New onset of fever, headache, or increase in nasal discharge following a viral upper respiratory tract infection lasting 5-6 days with some initial improvement

Note: Antibiotics are recommended when a patient presents with any of these symptom types (ie, persistent symptoms, severe symptoms at onset, or worsening symptoms).

Data from Reference 29.

Assess the Patient

- ③④③ Is the cough acute, subacute, or chronic? Although all coughs are acute initially, the duration of the cough at the time the patient seeks help from a healthcare provider aids in identifying a possible diagnosis (Table e13-1). Respiratory tract infections are the most common cause of acute cough. Subacute cough is most likely a postinfectious cough, followed by exacerbations of underlying diseases. There are several causes of chronic cough with asthma, UACS, NAEB, and GERD representing the most common causes of chronic cough in adult nonsmokers. Asthma, UACS, and GERD may present with additional symptoms consistent with the disease (eg, wheezing, rhinitis, and heartburn, respectively), but they may also present in a "silent" form with cough as the only symptom. Cough worsening during the night is suggestive of UACS.

- Does the patient have any red flag symptoms which are potentially life-threatening and require immediate referral to a physician (Table e13-5)?
- Does the patient have dyspnea? Numerous conditions can cause dyspnea, and the assessment of dyspnea should be conducted by the patient's primary care provider (Table e13-8).
- Does the patient meet diagnostic criteria for sinusitis based on the presence of at least two major symptoms or one major symptom in combination with at least two minor symptoms (Table e13-6)? Does the patient's clinical presentation suggest acute bacterial rhinosinusitis (Table e13-7)?
- Does the patient have any active medical problems that are associated with chronic cough (Table e13-2)?
- Does the patient have any family members with a history of allergies? Do any family members smoke?
- Does the patient have any exposure to occupational or environmental contributors to cough? Does the onset of the cough correlate to presence in the work environment? Cough related to an occupational or environmental stimulus may simply be an isolated symptom resulting from exposure to an irritant, or it may be a manifestation of more significant underlying disease.
- If applicable, assess readiness to quit smoking. If cough is present in a child, is the child exposed to secondhand smoke?
- Are any immunizations indicated (eg, influenza, pneumococcal, diphtheria, tetanus, acellular pertussis)?
- Not all patients with GERD-induced cough have gastrointestinal symptoms. Before suspecting GERD-induced cough in patients without heartburn or regurgitation symptoms, the patient should have an unremarkable chest radiograph, and the following conditions should be ruled out: (1) environmental and occupational irritants (including smoking); (2) medication-induced cough; (3) asthma (cough does not improve with short-acting beta-agonist and inhaled corticosteroids); (4) UACS (cough does not improve after a trial of first-generation antihistamines and intranasal corticosteroids); and (5) nonasthmatic eosinophilic bronchitis (evaluate for presence of eosinophils in sputum or cough that does not improve after a trial of inhaled corticosteroids).
- Is the patient able to access and afford their medications and adhere to their current medication regimen?
- Does the patient have an indication for all of their medications? Does the patient have an active medical problem associated with chronic cough that is not optimally treated?
- If applicable, estimate creatinine clearance to assess dosing of current or new medications.
- Is the patient taking any medications associated with cough (especially ACE inhibitors; see Table e13-4 for additional examples)?

TABLE e13-8

Examples of Conditions and Causes of Dyspnea Organized by Physiological Mechanism

Increased respiratory drive (increased afferent input to respiratory centers)	Stimulation of pulmonary receptors (irritant, mechanical, vascular)
	Interstitial lung disease
	Pleural effusion
	Pulmonary vascular disease (eg, thromboembolism, idiopathic pulmonary hypertension)
	Congestive heart failure
	Stimulation of chemoreceptors (conditions leading to acute hypoxemia, hypercapnia, and/or acidosis)
	Impaired gas exchange (eg, asthma exacerbations, COPD exacerbations, severe pulmonary edema)
	Impaired ventilator pump (eg, muscle weakness, airflow obstruction)
	Metabolic acidosis (eg, renal failure, renal tubular acidosis)
	Decreased oxygen-carrying capacity (eg, anemia)
	Decreased release of oxygen to tissues (eg, hemoglobinopathy)
	Decreased cardiac output
	Pregnancy
	Behavioral factors (eg, hyperventilation syndrome, anxiety disorders, panic attacks)
Impaired ventilator mechanics (reduced afferent feedback for a given efferent output)	Airflow obstruction (eg, asthma, COPD, laryngospasm, aspiration of foreign body, bronchitis)
	Muscle weakness (eg, myasthenia gravis, Guillain-Barré syndrome, spinal cord injury, myopathy, post-poliomyelitis syndrome)
	Decreased compliance of the chest wall (eg, severe kyphoscoliosis, obesity, pleural effusion)

Data from Reference 30.

Plan for Treatment or Referral

- When appropriate, coordinate care with the primary care provider and other healthcare team members to reach consensus on the proposed care plan.
- ④ If cough is accompanied with dyspnea, the patient should be referred to their primary care physician for a more extensive patient assessment.

Patients with red flag symptoms should also be immediately referred to their primary care provider for evaluation (Table e13-5).

- If the patient is exposed to environmental or occupational contributors to chronic cough, refer patient to a primary care provider for objective testing (eg, pulmonary function tests, rhinolaryngoscopy, methacholine challenge, sputum cytology, immunologic tests, beryllium lymphocyte proliferation tests).
- If the patient is ready to quit smoking, recommend appropriate nonpharmacotherapy and pharmacotherapy for smoking cessation (see Chapter 86, “Substance Use Disorders II: Alcohol Nicotine and Caffeine”).
- If the patient is not moderately or acutely ill, encourage appropriate immunizations if not contraindicated (eg, influenza, pneumococcal, diphtheria, tetanus, acellular pertussis; see Chapter 147).
- If an asthma exacerbation is suspected as the cause of acute, subacute, or chronic cough, stepping up therapy to improve asthma control may be considered (see Chapter 44).

Acute Cough

- If the patient has an acute cough suspected to be related to an acute respiratory tract infection, there are several therapeutic considerations.
    - If acute cough is suspected to be associated with acute bacterial rhinosinusitis, refer patient to their primary care physician for further evaluation and treatment (Tables e12-6 and e12-7; see Chapter 130, “Upper Respiratory Tract Infections”).
    - Acute cough from a viral respiratory tract infection is self-limiting with symptoms resolving within 7 days for most patients. For adult patients, a strong body of evidence to support or refute the routine or broad use of over-the-counter medications is lacking (ie, antitussives, expectorants, mucolytics, antihistamines, acetaminophen, NSAIDs). Swallowing associated with the use of lozenges may help suppress cough, and the soothing effect of lozenges, syrups, and honey may mitigate throat irritation. A combination product containing dextromethorphan, doxylamine, acetaminophen, and ephedrine is effective in reducing cough in adults. Dextromethorphan may also be effective in adult patients. Zinc lozenges (>75 mg/day) may reduce the duration of cough symptoms when given within 24 hours of symptom onset. For pediatric patients greater than 1 year old, honey and vapor rubs containing camphorated oils may be useful. Honey may contain *Clostridium botulinum* spores, and an infant’s immature digestive system contributes to the development of botulism. Therefore, honey is not recommended until a child is at least 1 year old. Dextromethorphan may provide relief from cough in pediatric patients but is not recommended in patients less than 2 years old. Cough medications containing codeine are not recommended for patients less than 18 years old due to the risk for respiratory adverse effects.

Subacute Cough

- If the patient has a subacute cough suspected to be a postinfectious cough, inhaled ipratropium may help reduce cough symptoms. If cough symptoms continue to adversely affect quality of life after a trial of inhaled ipratropium, inhaled corticosteroids may be considered. For severe cough, a 5 to 7 day course of oral corticosteroids may be considered (eg, prednisone 40 mg once daily for 5 days). If these therapeutic options do not provide adequate relief from cough, centrally acting antitussive medications (eg, codeine, dextromethorphan) may be considered.

Chronic Cough

- ⑤ If UACS is suspected as a contributing factor of chronic cough, a therapeutic trial of first-generation antihistamines and/or intranasal corticosteroids may be considered (see Chapter e14, “Allergic Rhinitis”).
- If the patient has chronic cough suspected to be related to GERD, treatment includes (1) diet modification to promote weight loss in overweight or obese patients; (2) nonpharmacologic treatment such as elevating the head of the bed and avoiding meals within 3 hours of bedtime; and (3) a 2- to 3-month trial of a proton pump inhibitor, H_2-receptor antagonist, or antacid therapy sufficient to control GERD symptoms (see Chapter 50, “Gastroesophageal Reflux Disease”). If the patient is not experiencing symptoms of GERD (eg, heartburn), pharmacotherapy for GERD is not recommended.

- ACE inhibitors should be discontinued since they may increase the severity of cough even when it is caused by other conditions. Angiotensin II receptor blockers (ARBs) serve as an alternative to ACE inhibitors since they have a lower risk of cough.

Additional General Considerations

- Ensure newly initiated medications do not have clinically significant drug–drug interactions with the patient's current medications. Alternatively, recommend dose adjustments or provide patient counseling for drug–drug interactions that can be managed.
- Identify the appropriate setting for follow-up (eg, face-to-face, phone) and schedule follow-up appointment in 4 to 6 weeks.

Implement by Making Recommendations to the Patient

- Provide patient education regarding all elements of the care plan.
- Ensure patient understanding and agreement with the care plan.
- Implement recommendations that are within your scope of practice.
- Communicate the care plan with the patient's healthcare team and provide recommendations to another healthcare team member that is outside your scope of practice.
- Document the patient encounter in the electronic health record.
- Communicate instructions for follow-up and schedule follow-up with the patient (eg, phone, face-to-face).

Follow-up by Monitoring and Evaluating Outcomes

- Patients should be reevaluated in 4 to 6 weeks and reassessed with the cough severity questionnaire (ie, CQLQ, LCQ, or PC-QOL) to evaluate outcomes.
- Assess patient's adherence to the care plan.
- If medications were changed at initial visit, assess for the presence of adverse effects.
- If the patient was not provided immunizations due to a moderate or acute illness at previous visit, encourage appropriate immunizations if not contraindicated and patient is not moderately or acutely ill at follow-up visit (eg, influenza, pneumococcal, diphtheria, tetanus, acellular pertussis; see Chapter 129, "Lower Respiratory Tract Infections").
- In patients with acute or subacute cough that persists for more than 8 weeks (ie, progresses to chronic cough), a trial of an oral first-generation antihistamine and/or intranasal corticosteroid may be recommended (ie, treatment trial for UACS).
- In patients with chronic cough that does not improve with an oral first-generation antihistamine and an intranasal corticosteroid (ie, treatment trial for UACS), refer patient to their primary care provider for ruling out asthma and NAEB before recommending a treatment trial for GERD.
- For GERD-induced cough, improvement in cough may take up to 3 months, even though GERD symptoms may improve within 4 to 8 weeks.
- For ACE inhibitor–induced cough, most patients will experience a reduction in cough within 8 weeks of discontinuing the ACE inhibitor. However, it may take up to 1 year for the cough symptoms to subside in some patients.

Data from References 3,11,15,22–32

CONCLUSION

Cough plays an important function in protecting the airways. However, alterations in this protective mechanism can result in clinically significant problems. There are many medications and a variety of diseases associated with the development of respiratory symptoms. Patients seek help from healthcare providers when cough symptoms cause significant impairment in functioning and adversely affect their quality of life. Classifying cough based on duration of symptoms is the first step in narrowing potential etiologies for cough. Some patients may present with symptoms that require immediate referral to their primary care provider. Alternatively, other health professionals may help patients select over-the-counter medications to mitigate acute and subacute cough associated with respiratory tract infections, or recommend a therapeutic trial for UACS or GERD in collaboration with the patient's primary care provider.

ABBREVIATIONS

ACE	angiotensin-converting enzyme
ARB	angiotensin II receptor blocker
COPD	chronic obstructive pulmonary disease
CQLQ	Cough Quality-of-Life Questionnaire
GERD	gastroesophageal reflux disease
LCQ	Leicester Cough Questionnaire
NAEB	nonasthmatic eosinophilic bronchitis
NSAIDs	nonsteroidal anti-inflammatory drugs
NTS	nucleus tractus solitaris
PC-QOL	Parent Cough-Specific Quality-of-Life Questionnaire
RAR	rapidly adapting receptors
SAR	slowly adapting receptors
TRPA-1	transient receptor potential ankyrin-1
TRPV-1	transient receptor potential vanilloid-1
UACS	upper airway cough syndrome

SELF-ASSESSMENT QUESTIONS

1. Which of the following symptoms is the second most common reason patients seek healthcare in ambulatory care settings?

   A. Cough

   B. Sneezing

   C. Sore throat

   D. Shortness of breath

2. Which of the following is an adverse consequence that can occur as a result of chronic cough?

   A. Asthma

   B. Irreversible loss of speech

   C. Myocardial infarction

D. Urinary incontinence

3. Which of the following is the most common cause of acute cough?

A. Chronic obstructive pulmonary disease

B. Gastroesophageal reflux disease

C. Heart failure exacerbations

D. Respiratory tract infections

4. Which of the following is the most common cause of subacute cough?

A. Bronchiectasis

B. Respiratory tract infections

C. Smoking

D. Upper airway cough syndrome

5. Which of the following is one of the most common causes of chronic cough in the United States?

A. Heart failure exacerbations

B. Lung cancer

C. Respiratory tract infections

D. Upper airway cough syndrome

6. Which of the following is a potential drug therapy target for new medications aimed at reducing cough?

A. Central alpha-2 receptors

B. Dipeptidyl peptidase-4

C. Peripheral beta-2 receptors

D. Transient receptor potential vanilloid-1

7. Which of the following is responsible for initiating a voluntary cough?

A. C-fiber receptors

B. Cortex

C. Nucleus tractus solitaris

D. Vagus nerve

8. Which of the following antihypertensive medications is most likely to cause cough?

A. Hydrochlorothiazide

B. Lisinopril

C. Metoprolol

D. Valsartan

9. Which of the following medications for the treatment of type 2 diabetes mellitus is most likely to cause cough?

    A. Insulin detemir

    B. Liraglutide

    C. Metformin

    D. Sitagliptin

10. Which of the following symptoms is considered a potentially life-threatening symptom that indicates need for referral to a physician for further evaluation?

    A. Cough

    B. Nasal congestion

    C. Shortness of breath at rest

    D. Sore throat

11. Which of the following is a validated questionnaire that is recommended to use at initial and follow-up appointments to assess health outcomes in adult patients complaining of cough symptoms?

    A. Asthma Quality of Life Questionnaire

    B. COPD Assessment Test

    C. Leicester Cough Questionnaire

    D. Parent Cough-Specific Quality of Life Questionnaire

12. Which of the following combinations of medications is most appropriate for a patient suspected of experiencing chronic cough due to upper airway cough syndrome?

    A. Albuterol inhaler and fluticasone inhaler

    B. Chlorpheniramine tablets and budesonide nasal spray

    C. Dextromethorphan syrup and zinc lozenges

    D. Omeprazole capsules and ranitidine tablets

13. LB is a 38-year-old African American female who complains of chronic cough as her only symptom. She failed to experience a significant improvement in scores on the Cough Quality-of-Life Questionnaire after a therapeutic trial for upper airway cough syndrome. Her primary care provider has ruled out asthma and nonasthmatic eosinophilic bronchitis using spirometry and sputum eosinophil count, respectively. Currently she is not taking any medications, and is not exposed to any environmental or occupational triggers for cough. Which of the following therapeutic trials would be most appropriate for LB?

    A. Albuterol inhaler

    B. Albuterol inhaler and beclomethasone inhaler

    C. Nonpharmacotherapy for gastroesophageal reflux disease (eg, elevating head of bed)

D. Nonpharmacotherapy for gastroesophageal reflux disease (eg, elevating head of bed) and lansoprazole

14. Which of the following clinical scenarios most likely indicates the need for referral to the patient's primary care provider for antibacterial treatment for acute bacterial rhinosinusitis?

A. A patient with cough, a temperature of 101°F (38.3°C), headache, and nasal congestion for 1 week with some improvement in symptoms

B. A patient with cough, a temperature of 101°F (38.3°C), nasal congestion, and fatigue for 3 days without improvement in symptoms

C. A patient with cough, nasal congestion, headache, and fatigue for 2 weeks without improvement in symptoms

D. A patient with cough, sneezing, nasal congestion, and clear rhinorrhea for 1 week without improvement in symptoms

15. When should patients return for follow-up to evaluate response to therapeutic approaches for the management of a cough that is not attributed to infection?

A. 1 to 2 weeks

B. 4 to 6 weeks

C. 3 to 5 months

D. 6 to 8 months

SELF-ASSESSMENT QUESTION-ANSWERS

1. **A.** Cough: This is the second most common reason patients report for seeking healthcare in ambulatory care settings, as described in the introduction of the chapter.

2. **D.** Urinary incontinence: Coughing can cause a loss of bladder control, as mentioned in the introduction of the chapter.

3. **D.** Respiratory tract infections: Viral infections of the upper respiratory tract are the most common cause of acute cough. See the "Epidemiology and Etiology" section of the chapter for more information.

4. **B.** Respiratory tract infections: Postinfectious cough is the most common cause of subacute cough. See the "Epidemiology and Etiology" section of the chapter for more information.

5. **D.** Upper airway cough syndrome: Asthma (including cough-variant asthma), upper airway cough syndrome, nonasthmatic eosinophilic bronchitis, and gastroesophageal reflux disease are the most common causes of chronic cough in adult nonsmokers with upper airway cough syndrome being the most common cause of chronic cough in the United States. See the "Epidemiology and Etiology" section of the chapter for more information.

6. **D.** Transient receptor potential vanilloid-1: Cough receptors have voltage-gated ion channels such as the transient receptor potential vanilloid-1. See the Anatomy and Mechanisms of Disease section of the chapter for more information.

7. **B.** Cortex: Cough sensory input travels from cough receptors to the respiratory center via the vagus nerve. The respiratory center consists of the nucleus tractus solitaris (NTS) and the cortex. See the Relevant Anatomy and Mechanisms of Disease section of the chapter for more information.

8. **B.** Lisinopril: As discussed in the Anatomy and Mechanisms of Disease section of the chapter, ACE inhibitors such as lisinopril are the most likely medications involved in causing cough.

9. **D.** Sitagliptin: As listed in Table e13-4, sitagliptin produces cough in about 5% to 6% of patients using the medication for management of diabetes.

10. **C.** Shortness of breath at rest: Cough associated with dyspnea at rest or at night is a red flag symptom that requires medical evaluation. Table e13-5 lists other symptoms that make self-care of cough inadvisable.

11. **C.** Leicester Cough Questionnaire: Adults and adolescent patients (>14 years of age) can complete either the Cough Quality-of-Life Questionnaire

or Leicester Cough Questionnaire to assess health outcomes, as discussed in the Patient Care Process section of the chapter. For children younger than 14 years of age, a parent or caregiver can complete the Parent Cough-Specific Quality of Life Questionnaire.

12. **B.** Chlorpheniramine tablets and budesonide nasal spray: A combination of a first-generation antihistamine and an intranasal corticosteroid is the preferred treatment for upper airway cough syndrome. For more information, see the Patient Care Process section of the chapter.

13. **C.** Nonpharmacotherapy for gastroesophageal reflux disease (eg, elevating head of bed) As discussed in the Patient Care Process section of the chapter, nonpharmacologic interventions should be attempted in patients suspected of having chronic cough associated with GERD, but pharmacotherapy for GERD is not recommended if the patient is not experiencing symptoms of GERD (eg, heartburn).

14. **C.** A patient with cough, nasal congestion, headache, and fatigue for 2 weeks without improvement in symptoms: These and other symptoms listed in Table e13-7 are "red flags" indicating possible acute bacterial rhinosinusitis and making self-care inadvisable. Instead, these patients should be evaluated by a medical professional.

15. **B.** Four to six weeks: As discussed in the Patient Care Process section of the chapter, patients should be reevaluated in 4 to 6 weeks and reassessed with a cough severity questionnaire.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e

Chapter e14: Allergic Rhinitis

J. Russell May

KEY CONCEPTS

KEY CONCEPTS

① Allergic rhinitis is a common disease. Prevention measures and treatment are justified in most cases because of the potential for complications.

② Because an immune response to allergens results in release of inflammatory mediators that cause allergic rhinitis symptoms, patients must understand the rationale for proper timing and administration of prophylactic regimens.

③ Avoidance of allergens is difficult and it may be impractical to expect full success.

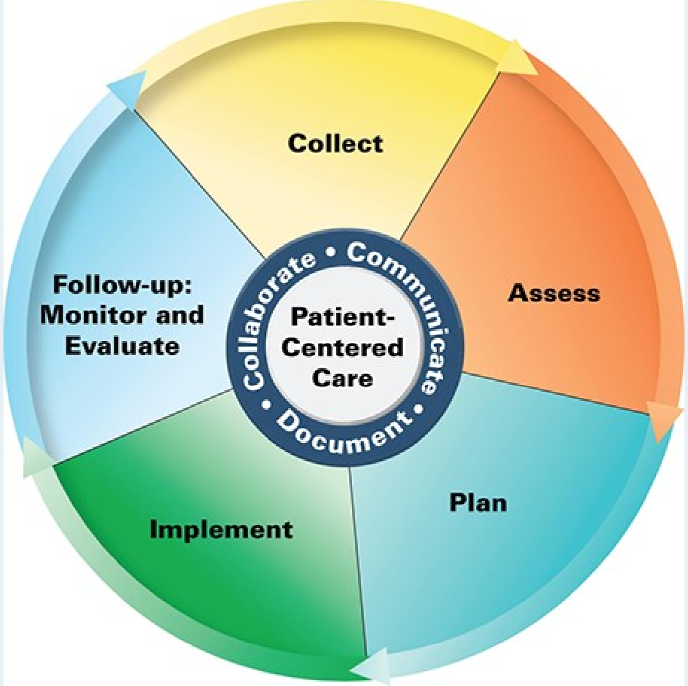
④ Antihistamines offer an effective option for treating both seasonal and persistent allergic rhinitis.

⑤ Intranasal steroids are highly effective in patients who use them properly.

⑥ While immunotherapy is the only disease-modifying treatment of allergic rhinitis, expense, potential risks, and the major time commitment required make patient selection critical.

PATIENT CARE PROCESS

Patient Care Process for Management of Allergic Rhinitis



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Primary complaint(s) (sneezing, clear rhinorrhea, postnasal drip, nasal congestion, ocular or otic symptoms, pruritic nose or palate)
- Patient characteristics (eg, age, race, sex, pregnant)
- Past medical history, allergy testing, medications
- Patient family, social history—dietary habits; presence of pets, mold, or wall-to-wall carpeting; times of year, situations, or locations (indoor or outdoor) when symptoms are worse
- Current over-the-counter (OTC) products, prescription medications, dietary supplements; past medications or interventions used for treating rhinitis symptoms
- Past or current use of environmental controls of potential allergens (eg, removal of carpeting or pets, air-filtration systems)
- Objective data
  - Presence of allergic “shiners” (dark circles under eyes) or “salute” (crease across nose caused by constant rubbing)
  - Labs when available (eg, immunoglobulin E [IgE], serum eosinophil count)
  - Other diagnostic tests when available (eg, allergy testing)

Assess

- Presence of concomitant atopic disorders (eg, asthma, atopic dermatitis)
- Presence of complications of allergic rhinitis (eg, acute otitis media, middle ear effusion, sinusitis, epistaxis)
- Timing of symptoms—seasonal or persistent (see Table e14-2)
- Usefulness for environmental controls of allergens (primarily for persistent cases)

- Which symptoms to control (eg, nasal congestion, clear rhinorrhea, sneezing, pruritus, ocular conjunctivitis)
- Current or past medications and patient response to those
- Appropriateness and effectiveness of current regimen

Plan[*]

- Nonpharmacologic interventions (eg, allergen avoidance, nasal rinses, nasal strips; see Table e14-3)
- Drug therapy regimen including specific agent(s), dose, route, frequency, and duration; specify the continuation and discontinuation of existing therapies (see Table e14-2 and Fig. e143-2)
- Patient education (eg, purpose of treatment, allergen avoidance, nonpharmacologic interventions, drug therapy, and the potential need for referral to physician or allergist for prescription or immunologic treatment).
- Self-monitoring of symptoms and adverse effects—where and how to record results
- Referrals to other providers when appropriate (eg, physician, allergist)

Implement[*]

- Provide patient education regarding all elements of treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence
- Schedule follow-up if needed

Follow-up: Monitor and Evaluate

- Monitoring parameters including efficacy (eg, bothersome symptoms), safety (eg, drowsiness, anticholinergic effects, effects on blood pressure; medication-specific adverse effects [see Table e14-8])
- Patient perception of control of bothersome symptoms
- Presence of adverse effects
- Continued presence of physical signs of nasal and ocular pruritus
- Patient adherence to treatment plan using multiple sources of information
- Referrals to other providers when appropriate (eg, physician, allergist)

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

Review the patient monitoring recommendations for the most common allergic rhinitis pharmacotherapy options (antihistamines, intranasal steroids, topical and systemic decongestants, mast cell stabilizers, and leukotriene receptor antagonists) in a standard drug information compendium (eg, Facts & Comparisons). This activity is useful to enhance student understanding of the PLAN step in the patient care process.

INTRODUCTION

Allergic rhinitis involves inflammation of the nasal mucous membrane. In a sensitized individual, allergic rhinitis occurs when inhaled allergenic particles contact mucous membranes and elicit a specific response mediated by immunoglobulin E (IgE). This acute response involves the release of inflammatory mediators and is characterized by sneezing, nasal itching, and watery rhinorrhea, often associated with nasal congestion. Itching of the throat, eyes, and ears frequently accompanies allergic rhinitis.

Allergic rhinitis may be regarded as seasonal allergic rhinitis, commonly known as *hay fever*, or persistent allergic rhinitis (formerly known as perennial rhinitis). Seasonal rhinitis occurs in response to specific allergens usually present at predictable times of the year, during plants' pollination (typically the spring or fall). Seasonal allergens include pollen from trees, grasses, and weeds. Persistent allergic rhinitis is a year-round disease caused by nonseasonal allergens, such as house dust mites, animal dander, and molds, or multiple allergic sensitivities. It typically results in less variable, chronic symptoms. Many patients have a combination of these two types of allergic rhinitis, with symptoms year-round and seasonal exacerbations.

EPIDEMIOLOGY AND ETIOLOGY

① Allergic rhinitis is one of the most common diseases affecting adults and is the most common chronic disease in children in the United States, generating $2 to $5 billion in direct healthcare cost each year.[1] Prevalence rates are 14% in adults and 13% in children when using a physician-confirmed diagnosis.[2] Actual sensitization to inhaled allergens is likely higher and is increasing with estimates of 15% to 30% in the United States.[3] Patients may be limited in their ability to carry out normal daily functions; higher levels of general fatigue, mental fatigue, anxiety, depressive disorders, and learning disabilities (secondary to sleep loss and fatigue) are possible.

In addition, the impact of allergic rhinitis goes well beyond these CNS issues. Allergic rhinitis is associated with several other serious medical conditions, including asthma, chronic rhinosinusitis, otitis media, nasal polyposis, respiratory infections, and orthodontic malocclusions.

The development of allergic rhinitis is determined by genetics, allergen exposure, and the presence of other risk factors. A family history of allergic rhinitis, atopic dermatitis, or asthma suggests that rhinitis is allergic. The risk of developing allergic disease appears to increase if one parent is atopic and further increases if two are allergic; however, small sample sizes and the lack of reproducibility prevent generalization.[4]

Allergen exposure is another necessary factor. For allergic rhinitis to occur, an individual must be exposed over time to a protein that elicits the allergic response in that individual. Many potential sufferers never develop symptoms because they do not come into contact with the allergen that would produce symptoms in them.

Microbial exposure in the first years of life could help prevent allergic disease by stimulating a nonatopic immune response.[5] Farm children are exposed to higher concentrations of endotoxin, derived from cell walls of gram-negative bacteria, in barns and dust around the farmhouse. Consumption of nonpasteurized farm milk may cause further exposure. These observations have led to the idea that allergic disease could be prevented by proactively increasing exposure to harmless bacteria early in life (see section "Alternative Treatment Options" below). This could explain why positive skin tests indicating allergen sensitization have been observed more frequently for people in higher income groups and for people who live in suburban areas.

Other predisposing factors include an elevated serum IgE (>100 international units/mL [kIU/L]) before the age of 6 years, eczema, and heavy exposure to secondhand cigarette smoke.[6]

Allergens that produce seasonal rhinitis include protein components of airborne pollen grains, often enzymes, from a variety of trees, grasses, and weeds. Ragweed and grass pollen are the most common offenders in the United States; however, this varies with the geographic region. In general, tree pollens cause symptoms in the spring, grass pollens cause symptoms in the late spring and summer, and weed pollens are the culprits from late summer through fall. Patients who are hypersensitive to all three may have overlapping problem periods and may be described as having persistent rhinitis when they are actually experiencing prolonged seasonal rhinitis. For this reason and the fact that most patients with seasonal problems are sensitive to at least some of the perennial allergens, there is little practical difference between the two types of allergic rhinitis. To complicate matters further, the antigenic components of many grasses—including fescue, Kentucky bluegrass, orchard, redtop, and timothy—cross-react extensively. By contrast, most tree allergens are antigenically distinct. Trees with allergenic pollen include ash, beech, birch, cedar, hickory, maple, oak, poplar, and sycamore. Flowering plants that depend on insect pollination do not cause allergic rhinitis because their pollen is too heavy and sticky and is not carried in the air.

Smaller mold spores are also important but cause allergy much less frequently. Various spores are present year-round; however, mold growth on decaying vegetation increases seasonally. Just walking through uncut fields or raking leaves can increase exposure. Thus, mold spores can be responsible for both perennial and seasonal allergies.

Indoor allergens are always present. Most important among these are house-dust mite fecal proteins, animal dander, cockroaches, and certain mold species. Dust mite levels are on the rise, possibly because of the construction of energy-efficient homes and offices with reduced ventilation and increased humidity, use of wall-to-wall carpeting, and the popularity of cool-water detergents and cold-water washing.[4]

PHYSIOLOGY AND MECHANISMS OF DISEASE

Knowledge of nasal physiology aids in the understanding of allergic rhinitis. The nose performs three "air conditioning" functions to prepare incoming gases for the lungs. During the fraction of a second that air is in the nose, it is heated, humidified, and cleaned. The cleaning process plays a role in the development of allergic rhinitis. As the air passes through the nose, the turbulence throws particulate matter against a mucous blanket. The rhythmic movements of the nasal cilia cause the mucous blanket to move posteriorly at approximately 9 mm/min, where it is eventually swallowed; thus, trapped foreign particles are removed via the GI tract and do not reach the lungs. It also concentrates foreign protein material into the posterior nasopharynx, where lymph tissues identify them and produce most of the allergic antibody that drives allergic rhinitis.

The vascular tissue in the nose is erectile. Stimulation of sympathetic fibers causes vasoconstriction, reduction in erectile tissue size and the size of the membranes and turbinates, and airway widening. Parasympathetic stimulation causes opposite effects.

Mast cells, in the nasal membranes, participate in the regulation of nasal patency by releasing mediators such as histamine. These are described below.

Immune Response to Allergens

② Allergic reactions in the nose are mediated by antigen–antibody responses when allergens interact with specific IgE molecules bound to nasal mast cells and basophils. In allergic people, these cells are increased in both number and reactivity. During inhalation, airborne allergens enter the nose and are processed by lymphocytes, which produce antigen-specific IgE, thereby sensitizing genetically predisposed hosts to those agents. Upon nasal reexposure, IgE bound to mast cells interacts with airborne allergen, triggering release of inflammatory mediators in vastly increased quantities (Fig. e14-1).[7]

FIGURE e14-1

Allergen sensitization and the allergic response. (*A*) exposure to antigen stimulates IgE production and sensitization of mast cells with antigen-specific antibodies. (*B*) Subsequent exposure to the same antigen produces an allergic reaction when mast cell mediators are released.

Both immediate- and late-phase reactions are observed after allergen exposure. The immediate reaction occurs within seconds to minutes, resulting in the rapid release of preformed mediators and newly generated mediators from the arachidonic acid cascade as the mast cell membrane is disturbed (Table e14-1). These mediators of immediate hypersensitivity include histamine, some leukotrienes, prostaglandin D_2, tryptase, and kinins.[7] In addition, the mast cell has been found to be a source of several cytokines that probably are relevant to the chronicity of the mucosal inflammation that characterizes allergic rhinitis.[8] Sensory nerve stimulation produces itching, and sneezing occurs via reflex stimulation of efferent vagal pathways. Neuropeptides substance P and calcitonin gene-related peptide from nonandrenergic, noncholinergic nerves affect vascular engorgement directly and via modulation of sympathetic tone. Histamine produces rhinorrhea, itching, sneezing, and obstruction, with the obstruction only partially blocked by H_1- or H_2-blocking agents.[9] Nasal obstruction is also caused by kinins, prostaglandin D_2, and leukotrienes C_4/D_4. Kinins, when directly administered, produce pain rather than itching.[10] These inflammatory mediators also produce vasodilation, increased vascular permeability, and production of increased nasal secretions.[11]

TABLE e14-1

Mast Cell Mediators

Mediators	Effects
Preformed and rapidly released histamine	Stimulates irritant receptors
	Pruritus
	Increased vascular permeability
	Increased mucosal permeability
	Smooth muscle contraction
Neutrophil chemotactic factor	Influx of inflammatory cells

Eosinophil chemotactic factor	Influx of inflammatory cells
Kinins	Increased vascular permeability
N-α-tosyl L-arginine methyl esterase	Increased vascular permeability
Newly generated	
Leukotrienes	Smooth muscle contraction
	Increased vascular permeability
	Mucus secretion
	Chemotaxis
	Neutrophil chemotaxis
Thromboxanes	Smooth muscle spasm
Platelet-activating factor	Mucus secretion
	Increased airway permeability
	Chemotaxis
	Increased vascular permeability
Granule matrix contents	
Heparin	Anti-inflammatory
Tryptase	Protein hydrolysis
Kallikrein	Protein hydrolysis

Four to eight hours after the initial exposure to an allergen, a late-phase reaction occurs symptomatically in 50% of allergic rhinitis patients.[12] This response, thought to be caused by cytokines released primarily by mast cells and thymus-derived helper lymphocytes, is characterized by profound infiltration and activation of migrating cells. This inflammatory response likely is responsible for the persistent, chronic symptoms of allergic rhinitis, including nasal congestion. The inflamed mucosa becomes hyper-responsive, a state characterized by exacerbation of nasal reactions to nonspecific or irritant triggers. In this state, the patient also reacts to increasingly lower amounts of the same allergen.[13] The process also causes significant increases in nonspecific irritability (as seen in asthma) and the notion among patients that they have become "allergic to everything."

PATIENT CARE PROCESS

Collect Information

The patient with allergic rhinitis typically complains of clear rhinorrhea, paroxysms of sneezing, nasal congestion, postnasal drip, and pruritic eyes, ears, nose, or palate. Symptoms of allergic conjunctivitis are associated more frequently with seasonal than persistent allergic rhinitis, because a majority of the perennial allergens, such as dust mites and molds, are indoors, where air velocity is too low for substantial deposition of allergenic particles on the conjunctivae. However, with heavy exposure from animal or mold allergens, allergic conjunctivitis can be pronounced.

Symptoms secondary to the late-phase reaction, predominantly nasal congestion, begin 3 to 5 hours after antigen exposure and peak at 12 to 24 hours. Subsequent symptoms, both allergic and irritant, are elicited more easily because of the priming effect. For instance, a ragweed-sensitive patient, when exposed to ragweed pollen out of season, responds with modest symptoms and may be very tolerant of irritants such as air pollution or tobacco smoke. During the ragweed season, however, when the nasal mucosa is already inflamed, exposure to small doses of pollen or to irritants to which the patient is usually tolerant elicits a response clinically indistinguishable from the patient's allergy.

Assess the Patient

Allergic rhinitis is distinguished from other causes of rhinitis by a thorough history, physical examination, and certain diagnostic tests. The medical history consists of a careful description of symptoms, environmental factors and exposures, results of previous therapy, use of other medications, previous nasal injuries, previous nasal or sinus surgery, family history, and the presence of other medical problems and medications. Historical identification of specific causative allergens may be difficult. For example, a reaction induced by mowing the lawn may not be caused by grass pollens but may be caused by the disturbance of various weeds, molds, or other plants in the lawn. With perennial allergic rhinitis, the cause-effect and temporal relationships are less clear, making the diagnosis of specific causes more difficult, especially with such covert allergens as house dust mites and molds.

In children, physical examination may reveal allergic shiners—a transverse nasal crease caused by repeated rubbing of the nose—and adenoidal breathing. Pale, bluish, edematous nasal turbinates coated with thin, clear secretions are characteristic of a purely allergic reaction. Tearing, conjunctival injection and edema, and periorbital swelling may be present. Physical findings are generally less clear-cut for adults.

Allergy testing can help determine whether a patient's rhinitis is caused by an allergen. Immediate-type hypersensitivity skin tests are used for the diagnosis of allergic rhinitis. These include skin tests performed by the percutaneous route, where the diluted allergen is pricked or scratched into the skin surface, or by the intradermal route, where a small volume (0.01-0.05 mL) of diluted allergen is injected between the layers of skin. Percutaneous tests are more commonly performed and are safer and more generally accepted, with intradermal tests reserved for patients requiring confirmation in special circumstances.

In all allergy testing, a positive control (histamine) and a negative control are essential for correct interpretation. After 15 minutes of the application of the allergen, the site is examined for a positive reaction (defined as a wheal-and-flare reaction). Because correct testing is done with extremely minute doses, undetectable by nonsensitized individuals, this reaction is evidence of the presence of mast cell–bound IgE specific to the allergen tested. Many, but not all, common allergens are available as standardized allergenic extracts.

Antihistamines and a few other medications interfere with the wheal-and-flare reaction. First-generation antihistamines should be stopped at least 3 to 5 days before testing, and second-generation, nonsedating antihistamines should be stopped at least 7 days before testing.[14] Medications with antihistamine properties (eg, sympathomimetic agents, phenothiazines, and tricyclic antidepressants) should be discontinued if possible before skin testing. The patient's physician should be contacted before stopping any prescription medications.

The radioallergosorbent test (RAST) was the first commonly used method for detecting IgE antibodies in the blood that are specific for a given allergen. Several other quantitative assays that include a reference curve calculated against standardized IgE are available. These tests are highly specific but may be slightly less sensitive than percutaneous tests.

Complications

Not only is allergic rhinitis aggravating, it frequently leads to further complications, particularly if the patient does not receive adequate treatment. Symptoms of untreated rhinitis may lead to disturbed sleep, chronic malaise, fatigue, and poor work or school performance. Patients often are plagued by loss of smell or taste, with sinusitis or polyps underlying many cases of allergy-related hyposmia. Postnasal drip with cough, hoarseness, and even vocal polyps also can be bothersome.

The role of allergic rhinitis in the development of acute otitis media or chronic middle ear effusion is often less clear. Children with allergic rhinitis appear to be at greater risk of these conditions because of nasal obstruction and negative middle ear pressure. Hearing problems in children related to middle ear effusion may lead to delayed development of language in young children or to school problems in older children.

Permanent facial disfigurement can result from chronic allergic rhinitis.[15,16] The chronic edema and venous stasis may contribute to the development of a high-arched, V-shaped palate. Mouth breathing caused by nasal obstruction can be responsible for dental malocclusion and orthodontic problems. Constant upward rubbing of the nose (allergic salute) can cause a transverse crease across the lower nose; nasal congestion often leads to venous pooling and dark circles under the eyes known as *allergic shiners*.

Allergic rhinitis is clearly associated with asthma. The prevalence of asthma in patients without rhinitis is less than 2%, while the prevalence of asthma in patients with rhinitis is 10% to 40%. It is not known if allergic rhinitis is an early clinical manifestation of asthma or if the nasal disease itself is causative for asthma.

Recurrent sinusitis and chronic sinusitis are relatively common complications of allergic rhinitis. The structure of the mucus blanket breaks down, with decreased water production by serous glands, leaving hair cells trapped in the thicker mucus layer. This greatly reduces the clearance of trapped bacteria and offers ideal breeding grounds for the bacteria. Nasal polyps are less common but nonetheless bothersome; they require specific therapy but may improve with management of the underlying allergic state. Epistaxis also can be a problem; it is related to mucosal hyperemia and inflammation.

Plan for Treatment or Referral

A number of options exist for the treatment of allergic rhinitis, both nonpharmacologic and pharmacologic. Many of the pharmacologic options are available OTC requiring that patients receive guidance in the selection process by a healthcare professional to obtain the most appropriate therapy. Both OTC and prescription choices must be guided by patient-specific symptomatology and patient characteristics as described in this chapter.

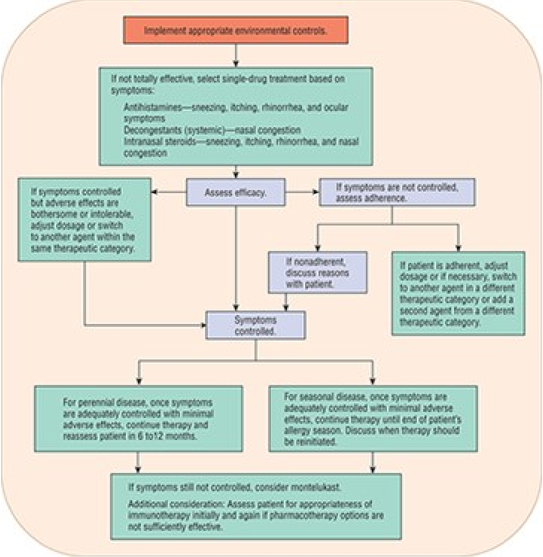
The therapeutic goal for patients with allergic rhinitis is to minimize or prevent symptoms and prevent long-term complications. This goal should be accomplished with no or minimal adverse medication effects and reasonable medication expenses. The patient should be able to maintain a normal lifestyle, including participating in outdoor activities, yard work, and playing with pets as desired.

General Approach to Treatment

Once the causative allergens and the specific symptoms are identified, management consists of three possible approaches: (a) allergen avoidance, (b) pharmacotherapy for prevention or treatment of symptoms, and (c) specific immunotherapy. The pharmacotherapy for symptoms approach includes several options that are based on patient-specific information (Table e14-2). Figure e14-2 depicts an algorithm for treatment options.

FIGURE e14-2

Treatment algorithm for allergic rhinitis.



Implement appropriate environmental controls.
If not totally effective, select single-drug treatment based on symptoms:
Antihistamines—sneezing, itching, rhinorrhea, and ocular symptoms
Decongestants (systemic)—nasal congestion
Intranasal steroids—sneezing, itching, rhinorrhea, and nasal congestion
If symptoms controlled but adverse effects are bothersome or intolerable, adjust dosage or switch to another agent within the same therapeutic category.
Assess efficacy.
If symptoms are not controlled, assess adherence.
If nonadherent, discuss reasons with patient.
If patient is adherent, adjust dosage or if necessary, switch to another agent in a different therapeutic category or add a second agent from a different therapeutic category.
Symptoms controlled.
For perennial disease, once symptoms are adequately controlled with minimal adverse effects, continue therapy and reassess patient in 6 to12 months.
For seasonal disease, once symptoms are adequately controlled with minimal adverse effects, continue therapy until end of patient's allergy season. Discuss when therapy should be reinitiated.
If symptoms still not controlled, consider montelukast.
Additional consideration: Assess patient for appropriateness of immunotherapy initially and again if pharmacotherapy options are not sufficiently effective.

TABLE e14-2

Pharmacotherapeutic Options for Allergic Rhinitis

Medication Classes	Symptoms Controlled	Comments
Antihistamines		
Systemic	Sneezing, rhinorrhea, itching, conjunctivitis	For seasonal allergic rhinitis, begin treatment before allergen exposure. Nonsedating agents should be tried first. If ineffective or too expensive for the patient, the older agents may be used. For perennial allergic rhinitis, use an intranasal steroid as an alternative to or in combination with systemic antihistamines
Ophthalmic	Conjunctivitis	Logical addition to nasal steroids if ocular symptoms are present
Intranasal	Sneezing, rhinorrhea, nasal pruritus	Option for seasonal allergic rhinitis. Warn patients of potential drowsiness
Decongestants		
Systemic	Nasal congestion	Only needed when nasal congestion is present
Topical	Nasal congestion	Only needed when nasal congestion is present. Do not exceed 3-5 days
Intranasal corticosteroids	Sneezing, rhinorrhea, itching, nasal congestion	For seasonal allergic rhinitis, an option when congestion is present. Must begin therapy before allergen exposure. Excellent choice for persistent allergic rhinitis
Mast cell stabilizers	See comments	Prevents symptoms; therefore, for seasonal allergic rhinitis, use before offending allergen's season starts. For persistent allergic rhinitis, improvement may not be seen for up to 1 month
Intranasal anticholinergics	Rhinorrhea	Reserve for use when above therapies fail or cannot be tolerated
Leukotriene receptor antagonists	See comments	When combined with antihistamines, more effective than antihistamines alone. May be used as monotherapy in children with asthma and coexisting allergic rhinitis

Nonpharmacologic Therapy

③ Avoidance of offending allergens is the most direct method of preventing allergic rhinitis, but it is often the most difficult to accomplish, especially for perennial allergens. Mold growth can be reduced by maintaining household humidity below 50% and removing obvious growth with bleach or disinfectant. Patients sensitive to animals will benefit most by removing pets from the home.[17] However, most animal lovers are reluctant to comply with this approach. Dog and cat allergens may produce symptoms in sensitized individuals.[8] After removing a cat from the home, it may take as long as

20 weeks for the home to reach allergen levels of a pet-free home. Washing cats weekly may reduce allergens but studies are inconclusive.[7] Some dogs display antigens more profusely than do others; clinically, a sensitized person may tolerate one animal better than another.

Evidence to support avoidance measures for house dust mites suggests that accepted notions for reducing exposure have little practical effect.[17] While some evidence shows allergen levels can be reduced by washing bedding on a hot cycle, replacing carpets with hard flooring and using vacuum cleaners with HEPA filters, there is no documented evidence for a clinical benefit. Only encasing bedding in impermeable covers has some clinical benefit in children but not adults. Future studies are needed to determine if environmental control of allergens may be helpful in forestalling further rhinitis and preventing later asthma.

General recommendations have been made to prevent poor air quality in homes.[18] Steps include avoiding wall-to-wall carpeting, using moisture control to prevent the accumulation of molds, and controlling sources of pollution such as cigarette smoke. Patients with seasonal allergic rhinitis should keep windows closed and minimize time spent outdoors during pollen seasons. Immediate hair washing and change of clothes are recommended upon returning indoors. Use of fans that direct outside air into the house should be avoided. Filter masks can be worn while gardening or mowing the lawn. Avoidance of upholstery and stuffed toys in the bedroom are easy steps to accomplish.

A couple of nonpharmacologic options available OTC can prove useful. Nasal saline irrigations represent a well-tolerated, inexpensive, and safe nonpharmacologic option for allergic rhinitis. Improvement in nasal symptoms and a reduction in medicine consumption have been demonstrated.[19] Adhesive nasal strips can facilitate breathing and can reduce nasal obstruction.[20]

Table e14-3 summarizes recommendations for environmental control and other nonpharmacologic options. These measures are intended to be a part of a comprehensive treatment strategy that will likely include pharmacotherapy and, in selected cases, immunotherapy.

TABLE e14-3

Nonpharmacologic Options for Allergic Rhinitis

Avoidance
Pollens • Keep windows and doors closed during pollen season • Avoid fans that draw in outside air • Use air conditioning • If possible, eliminate outside activities during times of high pollen counts • Shower, shampoo, and change clothes following outdoor activity • Use a vented dryer rather than an outside clothesline
Molds • Use similar controls as above • Avoid walking through uncut fields, working with compost or dry soil, and raking leaves • Clean indoor moldy surfaces • Fix all water leaks in home • Reduce indoor humidity to <50% if possible
House dust mites • Encase mattress, pillow, and box springs in an allergen-impermeable cover • Wash bedding in hot water weekly • Remove stuffed toys from bedroom • Minimize carpet use and upholstered furniture • Reduce indoor humidity to <50%, if possible

Animal allergens (if removal of pet is not acceptable) • Keep pet out of patient's bedroom • Isolate pet from carpet and upholstered furniture • Wash pet weekly
Cockroaches • Keep food and garbage in tightly closed containers • Take out garbage regularly • Clean up dirty dishes promptly • Use roach traps
Other recommendations • Do not allow smoking around the patient, in the patient's house, or in the family car • Minimize the use of wood-burning stoves and fireplaces
Over-the-counter options
Saline Rinses • Products include sodium chloride packets that are placed in containers or squeeze bottles and diluted then used to irrigate the nasal passages and sinuses.
Nasal Strips • Adhesive strips used externally on the nose to widen the nasal passages

Data from References 4, 19, and 20.

Pharmacologic Therapy

Table e14-4 summarizes the guidelines for treatment of allergic rhinitis with levels of evidence for each treatment strategy.[1,21] Therapeutic modalities for treating allergic rhinitis are generally directed at relief of symptoms as previously described in Table e14-2. Historically, antihistamines and decongestants (both oral and topical) were generally used first in treating allergic rhinitis with medications. Several options in these two categories are available without a prescription, but patients will need sound advice to make appropriate choices. Knowledge of pathophysiology, the inflammatory state, and analysis of published evidence has led to moving intranasal steroids to an option for first-line therapy. Several products are available OTC. Patients should receive counseling on the use of intranasal steroids to maximize their effects as described in the below Implement section.

TABLE e14-4

Evidence-Based Treatment Recommendations for Allergic Rhinitis

Recommendation	Level of Evidence[a]
Environmental factors	B
• Avoidance of known allergens	

• Environmental controls (removal of pets, air filters)	
• May consider this approach as optional	
Note: Even though good evidence exists, this may be hard to achieve.	
See text for limitations of this approach.	
Nasal steroids	A
• Benefits include symptom control, improved quality of life, better sleep, cost-saving if used as monotherapy, targeted local effect. Patient preference will play a large role.	
Oral antihistamines	A
• Second-generation (nonsedating) agents should be used in patients with primary complaints of sneezing and itching. Relief of eye symptoms, OTC status, and the availability of lower cost generics may be advantages.	
Intranasal antihistamines	A
• Evidence is strong but studies were of short duration. May consider these agents as optional.	
Oral leukotriene receptor antagonists	D
• For initial treatment of seasonal allergic rhinitis in patients >15 years, an intranasal steroid should be recommended over this class. (strong recommendation).	
• Clinicians should not recommend these agents as primary therapy for allergic rhinitis.	
• Patients with allergic rhinitis and asthma may benefit from this therapy.	
Combination therapy	Variable
• Oral antihistamines and oral decongestants: Several studies show benefit but must be weighed against potential risks: increased insomnia, headache, dry mouth, nervousness, and increased blood pressure. Tolerance may develop with long-term use of oral decongestants.	
• Oral antihistamines and intranasal steroids: No evidence to support the combination. For initial treatment of seasonal allergic rhinitis, monotherapy with an intranasal steroid rather than a combination should be used (strong recommendation).	
• Intranasal steroids and intranasal antihistamines: For patients who tolerate a nasal agent but have inadequate control of symptoms with a single agent, this combination is an effective option.	

- Intranasal steroids and topical decongestants: Combination more effective than intranasal therapy alone; however, see text regarding risk of rhinitis medicamentosa.	
Immunotherapy	
- Recommended in patients who have inadequate response to with pharmacologic therapy with or without environmental controls	A
- See text for information on sublingual versus subcutaneous therapy	

[a] Levels of evidence: A, a strong recommendation or recommendation based on excellent evidence where benefits clearly outweigh harms. B, a strong recommendation or recommendation based on good evidence that benefits outweigh harms. C, recommendation where evidence is not as strong or high-quality evidence is impossible to obtain. D, an optional therapy for some patients but quality of evidence is suspect, or no recommendation because there is a lack of pertinent evidence and an unclear balance between benefits and harm. For each level of evidence, see comments for further clarification of recommendations.

TABLE e14-5

Relative Adverse-Effect Profiles of Antihistamines

Medications	Relative Sedative Effects	Relative Anticholinergic Effects
Alkylamine class, nonselective		
Brompheniramine maleate	Low	Moderate
Chlorpheniramine maleate	Low	Moderate
Dexchlorpheniramine maleate	Low	Moderate
Ethanolamine class, nonselective		
Carbinoxamine maleate	High	High
Clemastine fumarate	Moderate	High
Diphenhydramine hydrochloride	High	High
Phenothiazine class, nonselective		
Promethazine hydrochloride	High	High
Piperidine class, nonselective		
Cyproheptadine hydrochloride	Low	Moderate
Phthalazinone class, peripherally selective		
Azelastine (nasal only)	Low to none	Low to none
Bepotastine (ophthalmic only)	Low to none	Low to none
Piperazine class, peripherally selective		
Cetirizine	Low to moderate	Low to none
Levocetirizine	Low to moderate	Low to none
Piperidine class, peripherally selective		
Desloratadine	Low to none	Low to none
Fexofenadine	Low to none	Low to none
Loratadine	Low to none	Low to none
Olopatadine (nasal only)	Low to none	Low to none

Antihistamines

④ Antihistamines are much more effective in preventing the actions of histamines and essentially do not reverse these actions once they have taken place. Reversal of symptoms is largely caused by the anticholinergic properties of these drugs. This activity is responsible for the drying effect of antihistamines, which reduces the problem of nasal, salivary, and lacrimal gland hypersecretion. Antihistamines antagonize increased capillary permeability, wheal-and-flare formation, and itching.

In general, the antihistamines are well absorbed, have large volumes of distribution, and are metabolized by the liver. Serum half-lives vary considerably between patients. In addition, the therapeutic effects of these agents are more prolonged than might be predicted by their half-lives.

Drowsiness is usually the chief complaint of patients who take antihistamines. It can interfere with a patient's ability to drive a car or operate machinery and may interfere with the patient's ability to function adequately at the workplace. Remember that these problems can also be a reflection of the disease itself. For this reason, many recommend the use of peripherally selective agents as first-line treatment for any patient who is at high risk for the development of adverse events. This includes patients with renal or hepatic impairment, those with small weights (for whom adult doses may provide larger-than-recommended doses on a milligram-per-kilogram basis), patients with preexisting CNS or cardiac disorders, patients who require higher doses, and patients who have shown a tendency to overuse nonprescription or prescription medications (Table e14-5).[22]

The sedative effects of antihistamines can be useful for patients who suffer from sleeplessness caused by the symptoms of allergic rhinitis. In these patients, a bedtime dose may prove beneficial. However, they may cause residual daytime sedation, decreased alertness, and performance impairment.

The logic of preferentially using the second-generation agents is not clear-cut. A meta-analysis of performance-impairment trials did not show a clear and consistent distinction between diphenhydramine and the peripherally selective agents.[23] Another study showed that tolerance to sedation secondary to diphenhydramine developed by day 4 of treatment, becoming indistinguishable from placebo,[24] but sedation must be distinguished from impairment since the two are not equivalent. Despite this evidence, guidelines recommend the nonsedating agents.[1,17]

Anticholinergic (drying) effects contribute to the agents' therapeutic efficacy, but they also cause most adverse effects. Dry mouth, difficulty in voiding urine, constipation, and potential cardiovascular effects may be troublesome. Keep in mind that the differences may be small. Patients with a predisposition to urinary retention (eg, older men and those on concurrent anticholinergic therapy) should use antihistamines with caution. Caution also should be used for patients with increased intraocular pressure, hyperthyroidism, and cardiovascular disease.

Other adverse effects of oral antihistamines include loss of appetite (and paradoxically, weight gain with increased appetite), nausea, vomiting, and epigastric distress.

Antihistamines are only fully effective when taken approximately 1 to 2 hours before anticipated exposure to the offending allergen. This must be discussed with patients who face exposure daily during a pollen season and with those who have indoor perennial allergens where daily scheduled use is necessary. If tolerance develops to the therapeutic effect, a change to an agent in a different chemical class is usually effective.

Patients should be counseled about the proper use of antihistamines. Adverse effects, especially drowsiness, should be emphasized. Patients should be warned against taking other CNS depressants, including the use of alcohol. Patients should be told not to take a double dose when a dose is missed. Taking the antihistamine with meals or at least a full glass of water will help prevent GI adverse effects such as nausea, vomiting, and epigastric distress. Patients should check with their healthcare professional and read labels before taking nonprescription medications. Many cold products and sleep aids contain antihistamines. Patients should be instructed not to use more than one antihistamine at a time. Table e14-6 lists the recommended dosages of the commonly used agents with their availability status (prescription only vs OTC).

TABLE e14-6

Medication Dosing for Allergic Rhinitis

Drugs	Dosages	Comments
Antihistamines		

Oral, nonselective		
Chlorpheniramine	*Adolescents and adults (>12 years)*	
	4 mg every 6 hours (plain)	OTC, available as liquid
	12 mg every 12 hours (extended release)	OTC
	Pediatrics	
	2-5 years: 1 mg every 4-6 hours	
	6-11 years: 2 mg every 4-6 hours	
Diphenhydramine	*Adolescents and adults (>12 years)*	
	25-50 mg every 4-6 hours	OTC, available as liquid
	(max = 300 mg daily)	
	Pediatrics (6-11 years only)	
	12.5-25 mg every 4-6 hours (max = 150 mg daily)	
Oral, peripherally selective		
Cetirizine	*Adolescents and adults (>12 years)*	
	5-10 mg once daily	OTC, available as liquid
	Pediatrics	
	6 months to 5 years: 2.5 mg daily	
	6 years to 11 years: 5-10 mg daily	
Fexofenadine	*Adolescents and adults (>12 years)*	
	60 mg every 12 hours or 180 mg once daily	OTC, available as liquid
	Pediatrics	
	2-11 years: 30 mg twice daily	
Levocetirizine	*Adolescents and adults (>12 years)*	
	5 mg once daily (in the evening)	Rx, available as liquid
	Pediatrics	
	6 months to 5 years: 1.25 mg daily (in the evening)	

	6-11 years: 2.5 mg daily (in the evening)	
Loratadine	*Adolescents and adults (>12 years)*	
	10 mg once daily	OTC, available as liquid
	Pediatrics	
	2-5 years: 5 mg daily	
	6 years and older: 10 mg once daily or 5 mg twice daily	
Intranasal	Note: dose is per each nostril	
Azelastine	*Adolescents and adults (>12 years)*	
	1-2 sprays once or twice daily (depending on brand)	Rx
	Pediatrics	
	6 months to 11 years: 1 spray twice daily	
Olopatadine	*Adolescents and adults (>12 years)*	
	2 sprays twice daily	Rx
	Pediatrics	
	6-11 years: 1 spray twice daily	
Ophthalmic		
Bepotastine	*Adolescents and adults (>12 years)*	
	1 drop to affected eye(s) twice daily	Rx
	Pediatrics	
	2-11 years: 1 drop to affected eye(s) twice daily	
Decongestants		
Oral		
Pseudoephedrine	*Adolescents and adults (>12 years)*	
	60 mg every 4-6 hours	OTC, available as liquid
	120 mg every 12 hours (sustained release)	
	240 mg every 24 hours (controlled release)	

	Pediatrics	
	2-5 years: 15 mg every 4-6 hours	
	6-11 years: 30 mg every 4-6 hours	
Phenylephrine	*Adolescents and adults (>12 years)*	
	10-20 mg every 4 hours	OTC, available as liquid
	Pediatrics	
	2-5 years: 2.5 mg every 4 hours	
	6-11 years: 5 mg every 4 hours	
Nasal	Note: dose is per each nostril	
Oxymetazoline	*Adolescents and adults (>12 years)*	
	2-3 sprays, twice daily (max = 3 days)	OTC
	Pediatrics	
	6–11 years: same as adult dose (max = 3 days)	
Phenylephrine	*Adolescents and adults (>12 years)*	
	2-3 sprays every 4 hours (max 3 days), 0.25%-1%	OTC
	Pediatrics	
	2-5 years: 2-3 sprays every 4 hours (max 3 days), 0.125%	
	6-11 years: 2-3 sprays every 4 hours (max 3 days), 0.25%	
Intranasal Steroids	Note: dose is per each nostril	
Beclomethasone	*Adolescents and adults* (>12 years)	
	42-84 mcg twice daily (42 mcg/spray)	Rx
	160 mcg once daily (80 mcg/spray)	
	Pediatrics	
	6-11 years: 42 mcg twice daily (42 mcg/spray)	
	4-11 years: 40 mcg once daily (40 mcg/spray)	
Budesonide	*Adolescents and adults (>12 years)*	

	32 mcg (1 spray) once daily	OTC
	Pediatrics	
	6-11 years: 32 mcg (1 spray) once daily	
Flunisolide	*Adolescents and adults (>15 years)*	
	50 mcg (2 sprays) twice daily	Rx
	May increase to three times daily	
	Pediatrics	
	6-14 years: 50 mcg (2 sprays) twice daily	
Fluticasone	*Adolescents and adults (>12 years)*	
	1-2 sprays once daily (either salt)	OTC
	Pediatrics propionate = 50 mcg/spray	
	4-11 years: 1 spray once daily (propionate) furoate = 27.5 mcg/spray	
	2-11 years: 1 spray once daily (furoate)	
Mometasone	*Adolescents and adults (>12 years)*	
	100 mcg (2 sprays) once daily	Rx
	Pediatrics	
	2-11 years: 50 mcg (one spray) once daily	
Triamcinolone	*Adolescents and adults (>12 years)*	
	110 mcg (2 sprays) once daily	OTC
	Pediatrics	
	2-11 years: 55 mcg (1 spray) once daily	
Other Nasal Medications	Note: dose is per each nostril	
Cromolyn	*Adolescents and adults* (>12 years)	
	5.2 mg (1 spray) three to four times daily	OTC
	Pediatrics	
	2-11 years: 5.2 mg (1 spray) three to four times daily	

Ipratropium	Persistent allergic rhinitis:	Rx
	Adolescents and adults (>12 years)	
	2 sprays (21 mcg/spray) 2 or three times daily	
	Pediatrics	
	6 years and older: 2 sprays (21 mcg/spray) two or three times daily	
	Seasonal allergic rhinitis	
	Adolescents and adults (>12 years)	
	2 sprays (42 mcg/spray) three or four times daily	
	Pediatrics	
	5 years and older: 2 sprays (42 mcg/spray) four times daily	
Leukotriene-Receptor Antagonist, oral		
Montelukast	*Adolescents and adults (>12 years)*	
	10 mg once daily	Rx
	Pediatrics	
	6-14 years: 5 mg once daily	
	2-5 years: 4 mg once daily	
	6-23 months: 4 mg once daily	

Many patients respond to and tolerate the older agents quite well. Because many of the older agents are available generically, they are much less expensive. Patient cost for many of the older nonprescription agents is less than $5 for a 30-day supply, compared with more than $20 for some of the nonprescription selective agents. Although cost is a concern, patient safety should be the first consideration.

The selective agents are preferred over nonselective antihistamines, according to a survey of pharmacists.[25] Among the 2 million antihistamine recommendations, the top three were loratadine (41%), cetirizine (33%), and fexofenadine (15%) followed by the nonselective agents diphenhydramine (9%) and chlorpheniramine (2%).

Intranasal or ophthalmic antihistamines are possible options but these products are available by prescription only. For seasonal and persistent allergic rhinitis, the intranasal antihistamine azelastine is available. The 0.1% product can be used in children for seasonal allergies, while the 0.15% product is labeled for adults only for either type of allergic rhinitis. Despite this labeling, recent guidelines favor the use of the intranasal route for seasonal but not persistent allergic rhinitis.[17] Azelastine has been used successfully for patients who did not respond to loratadine.[26] Using the nasal route offers an alternative to switching to another oral antihistamine. Patient satisfaction has been varied because while the product produces rapid symptom relief, patients complain of drying effects, headache, and diminished effectiveness over time. Patients should be warned of the medication's potential to produce drowsiness, as its systemic availability is approximately 40%.[27,28] Olopatadine, another intranasal antihistamine, may cause less drowsiness as it is a selective H_1-receptor antagonist.

Allergic conjunctivitis, often associated with allergic rhinitis, can be treated with ophthalmic antihistamines such as levocabastine or bepotastine. Because systemic antihistamines usually are also effective for allergic conjunctivitis, one of these ophthalmic agents may be a logical addition to nasal steroids when ocular symptoms occur.

Decongestants

Topical and systemic decongestants are sympathomimetic agents that act on adrenergic receptors in the nasal mucosa, producing vasoconstriction. Decongestants shrink swollen mucosa and improve ventilation. When nasal congestion occurs with allergic rhinitis, decongestants work well in combination with antihistamines.

Topical Decongestants

Topical decongestants are applied directly to swollen nasal mucosa via drops or sprays. Table e14-7 lists the common topical decongestants and their durations of action. The use of these agents results in little or no systemic absorption.

TABLE e14-7

Duration of Action of Topical Decongestants

Medications	Durations of Action (hours)
Short acting	
Phenylephrine hydrochloride	Up to 4
Intermediate acting	
Naphazoline hydrochloride	2-6
Tetrahydrozoline hydrochloride	
Long acting	
Oxymetazoline hydrochloride	Up to 12
Xylometazoline hydrochloride	

Because these agents are extremely effective and are available to patients without a prescription, they are widely used. However, prolonged use of these agents (for more than 3-5 days) can result in a condition known as *rhinitis medicamentosa*, or *rebound vasodilation*, with even more severe congestion. Patients who develop this condition use increasingly more spray more often with less response. Although the methods used to treat this “addiction” have not been studied formally, several are used commonly. Abrupt cessation works, but it is difficult because of rebound congestion that may leave the patient congested for several days or weeks. Sleeping may become difficult. Nasal steroids have been used successfully, but they take several days to work. Weaning the patient off topical decongestants can be accomplished by decreasing the dosing frequency or the concentration over several weeks. Combining the weaning process with nasal steroids may prove useful. Ultimately, the success of any plan depends on the patient’s resolve and clear understanding of the importance of stopping the drug to end the problem.

Other adverse effects of topical decongestants include burning, stinging, sneezing, and dryness of the nasal mucosa.

Patients should be counseled on the use of topical decongestants to prevent rhinitis medicamentosa. Patients should be instructed to use as small a dose as possible as infrequently as possible and only when absolutely necessary (eg, at bedtime to aid in falling asleep). Duration of therapy always should be limited to 3 days or less.

Systemic Decongestants

Oral decongestants are not as effective on an immediate basis as the topical agents, but their effects sometimes last longer and they cause less local irritation. In addition, rhinitis medicamentosa is not a problem with oral agents. The most commonly used agent is pseudoephedrine. Table e14-6 lists the usual doses for the regular and sustained-release versions. The use of phenylephrine is increasing because of regulations related to pseudoephedrine described below.

Concerns of safety have greatly limited the systemic decongestant options. Legal requirements for the sale of pseudoephedrine were put into place to combat the misuse of the drug as a component in making methamphetamine. Pseudoephedrine must now be sold behind the counter, and the monthly amount a patient can purchase is limited. Until this requirement, pseudoephedrine was the most frequently used systemic decongestant, and it was considered the safest. Doses of 180 mg produce no measurable change in blood pressure or heart rate.[29] In higher doses (210-240 mg), pseudoephedrine has raised both blood pressure and heart rate.[30] Pseudoephedrine can cause mild CNS stimulation, even at therapeutic doses. Stroke, related to use of oral decongestants such as pseudoephedrine, can occur in patients with hypertension and/or vasospasm.[31] Although stroke complications seem to be associated with higher-than-recommended doses, there is also a stroke risk when these agents are taken properly. Severe hypertensive reactions can occur when pseudoephedrine is given concomitantly with monoamine oxidase inhibitors. Hypertensive patients should, unless necessary, avoid systemic decongestants.

Combination Products

Numerous products combine an antihistamine with a decongestant. While the combination may be rational because of the different mechanisms of action, remember that antihistamines must be taken on a regular schedule, but decongestants should only be used when needed. Both nonselective and peripherally selective antihistamines are available in such combinations. As mentioned previously, patients should read labels to avoid therapeutic duplication. Consideration should be given to how often and how severely the patient is congested before recommending these combinations. Only a short course of a combination product should be used.

Nasal Steroids

⑤ Nasal steroids are an excellent choice for treating persistent rhinitis, and can be an excellent choice in seasonal rhinitis, especially if begun in advance of symptoms. Nasal steroids appear to be effective with minimal adverse effects. Recent guidelines suggest that nasal steroids should be recommended as initial therapy.[21] Multiple mechanisms are involved with the effects of nasal steroids on the nasal mucosa: reducing inflammation by reducing mediator release, suppressing neutrophil chemotaxis, reducing intracellular edema, causing mild vasoconstriction, and inhibiting mast cell-mediated late-phase reactions. Table e14-6 lists the available nasal steroids and their usual doses.

Topical steroids produce only minor adverse effects, most commonly sneezing, stinging, headache, and epistaxis. Despite concerns about safety of systemic steroids, nasal steroids have been found to have no significant association with hypothalamic–pituitary axis suppression, cataract formation, glaucoma, or bone mineral density changes in the doses used for allergic rhinitis. Growth suppression remains a question with some evidence showing that nasal steroids with higher bioavailability (eg, beclomethasone) may have a greater growth-suppression effect than less bioavailable agents.[32] These findings require more study. Most likely, all currently available nasal steroids are safe in the majority of patients, and their clinical benefits outweigh any small growth suppressive effect. Other concerns include local infections with *Candida albicans*, which occur rarely.

Patient preference studies suggest some patients tolerate the fluticasone furoate better than fluticasone propionate or mometasone in characteristics such as taste, odor, gentleness, and nasal irritation.[34] While fluticasone furoate is more expensive, it should be considered if patients complain about these characteristics of the other products.

The therapeutic benefits of topical steroids are not immediate, and they are not decongestants. Patients need to understand this to ensure cooperation and continuation of therapy. Some patients notice improvement in a few days, but peak responses may not be observed for 2 to 3 weeks. Once a response is achieved, the dosage may be reduced. Blocked nasal passages should be cleared with a decongestant or saline irrigation before administration to ensure adequate penetration of the spray. Patients should be advised to avoid sneezing or blowing their noses for at least 10 minutes after administration. Topical steroids should not be used for patients with nasal septum ulcers or recent nasal surgery or trauma.

One additional benefit of nasal steroids in treating allergic rhinitis in individuals with asthma and upper airway conditions is that they may confer some protection against exacerbations of asthma, leading to fewer emergency room visits. The overall relative risk for an emergency visit among asthma patients who received intranasal steroids was 0.7.[33] No effect was seen for patients receiving antihistamines.

Other Inhalant Medications

Cromolyn sodium and ipratropium bromide offer two additional approaches for treating allergic rhinitis. While neither of these agents appears in the latest treatment guidelines, they are mentioned here for completeness. Cromolyn sodium is a mast cell stabilizer. Increased interest in this product has resulted from it becoming available without a prescription. Ipratropium bromide is an anticholinergic agent that may be useful in perennial allergic rhinitis.

Cromolyn sodium nasal spray is used for the symptomatic prevention and treatment of allergic rhinitis. It curtails antigen-triggered mast cell degranulation and release of the mediators of allergic reactions, including histamine. Cromolyn sodium has no direct antihistaminic, anticholinergic, or anti-inflammatory properties. Similarly to topical steroids, the most common adverse effects—sneezing and nasal stinging—result from local irritation. Dosing information is given in Table e14-6. Cromolyn sodium must cover the entire nasal lining; therefore, patients should be instructed to clear nasal passages before administration. Inhaling gently through the nose during administration aids in this process. Dosing must be repeated at 6-hour intervals to maintain the effect.

For seasonal rhinitis, treatment with cromolyn sodium should be initiated just before the usual start of the offending allergen's season and continued throughout the season. In perennial rhinitis, the effects may not be seen for 2 to 4 weeks; therefore, antihistamines or decongestants may be needed during this initial phase of therapy. As cromolyn sodium begins to work, the need for these medications should decrease.

Ipratropium nasal spray is an anticholinergic agent that exhibits antisecretory properties when applied locally. It provides symptomatic relief of rhinorrhea associated with allergic and other forms of chronic rhinitis. Dosing information is given in Table e14-6. The optimal dose should be determined based on the specific patient's symptoms and response. Adverse effects are mild, with the most common being headache, nosebleeds, and nasal dryness.

Immunotherapy

⑥ Experience with immunotherapy has reached the one-century mark, as the first report of the successful use of grass pollen extract injections to treat allergic rhinitis was published in 1911.[34] Until recently, immunotherapy was only available for via subcutaneous injections. Sublingual dosage forms are now available for a very limited number of antigens as will be described later. The therapy was first called *desensitization*; however, this did not seem appropriate because skin reactivity sometimes remained. The name was later changed to *hyposensitization*. Although this term is still used today, *immunotherapy* is used more commonly and is less confusing.

Immunotherapy is the process of administering doses of antigens responsible for eliciting allergic symptoms into a patient with the hope of inducing tolerance to the allergen when natural exposure occurs. Several mechanisms have been proposed to explain the beneficial effects of immunotherapy, including induction of IgG-blocking antibodies, reduction in specific IgE (long-term), reduced recruitment of effector cells, altered T-cell cytokine balance (a shift from T-helper type 1 to T-helper type 2), T-cell anergy, and alteration of regulatory T-cell actvitiy.[35]

Immunotherapy is moderately expensive, has significant potential risks, and for subcutaneous therapy, a major time commitment is required from the patient. However, the cost of immunotherapy may be covered by insurance, including Medicaid. Long-term savings can be realized since decades of treatment with medication can be averted through successful immunotherapy. Candidates for immunotherapy should have significant symptoms unsuccessfully controlled by avoidance and pharmacotherapy or should stand to benefit in other significant ways, such as with asthma. Immunotherapy may postpone the onset of asthma or possibly even prevent it.[36] Patients who are unable to tolerate the adverse effects of properly managed drug therapy also should be considered. Patients must be committed to the necessary regular office visits required to complete a course of subcutaneous therapy over several years.

The effectiveness of immunotherapy for seasonal allergic rhinitis appears to be better than that seen with persistent rhinitis, in part because it is more difficult to determine which allergen is responsible for persistent symptoms, and it is more often due to multiple sensitizations. Effectiveness has been shown in a number of clinical studies using a variety of pollen extracts, even for patients with severe disease resistant to pharmacotherapy.[36] Data indicate that for some patients, 3 years of subcutaneous immunotherapy may be sufficient to give lasting benefit[37]; however, many require longer treatment.

The selection of antigens should be based on patient history and skin test results. Numerous regimens for administration of selected allergens have been suggested. In the beginning of subcutaneous immunotherapy, very dilute solutions are given initially to one to two times per week. The concentration is increased until the maximum tolerated or highest planned or effective dose is achieved. This maintenance dose is continued in slowly increasing intervals over several years, depending on clinical response. Because of the present understanding of the immunologic results of immunotherapy, it should be given year-round rather than seasonally.

Sublingual dosage forms for a very limited number of allergens are now available in the United States. Sublingual immunotherapy is available for ragweed and certain grass allergies. Because the types of allergens are limited, patient selection should be done carefully to ensure that those receiving this route of immunotherapy are the most likely to benefit. These products are started 12 weeks before the allergen season and continued throughout the season. House dust mite allergen is available in the United States. Because house dust mites cause persistent allergic rhinitis, this product is given year round. The first dose is administered in the physician's office to allow observation of the patient for 30 minutes for hypersensitivity reactions. The patient places the tablet under the tongue where it dissolves. Patients should not swallow for at least 1 minute. After the first dose is administered without incident, patients can take sublingual immunotherapy at home. However, patients must be prescribed an autoinjectable epinephrine.

Adverse reactions can occur with immunotherapy and range from mild to life threatening. Among the most common are mild local reactions with subcutaneous injections, consisting of induration and swelling at the site of the injection. These may be immediate or delayed. Other more serious reactions (eg, generalized urticaria, bronchospasm, laryngospasm, and vascular collapse) occur rarely; deaths can result from anaphylactic reactions. Severe reactions are treated with epinephrine as well as other modalities recommended for anaphylaxis. Because of this potential risk, subcutaneous immunotherapy should not be given without adequate direct observation in a medical facility. With sublingual immunotherapy, the most common reactions are pruritus of the mouth, ears, and tongue, throat irritation, and mouth edema.

Several patient types are poor candidates for immunotherapy, including patients with any medical condition that would compromise the ability to tolerate an anaphylactic-type reaction, patients with impaired immune systems, and patients with a history of nonadherence to therapy. Sublingual immunotherapy is only approved for patients 18 years and older.

Leukotriene Receptor Antagonists

Leukotriene receptor antagonists inhibit the cysteinyl leukotriene receptor. The cysteinyl leukotrienes are one type of inflammatory mediators released from mast cells in allergy. Montelukast is approved for the treatment of perennial allergic rhinitis in children as young as 6 months and for seasonal allergic rhinitis in children as young as 2 years. Montelukast is considered a third choice behind antihistamines and nasal steroids.[17]

Leukotriene receptor antagonists are no more effective than peripherally selective antihistamines and less effective than intranasal steroids. However, when combined with antihistamines, they are more effective than the antihistamine alone.[38] In children with mild persistent asthma and coexisting allergic rhinitis, montelukast as monotherapy has been recommended.[1] Table e14-6 lists dosage regimens.

Alternative Treatment Options

A few other alternative options have been suggested for treatment of allergic rhinitis. As mentioned earlier in this chapter, microbial exposure in the early years of life could help prevent allergic disease by favoring a nonatopic immune response.[5] However, the use of probiotics may be limited to treatment or prevention of childhood eczema as available evidence shows little benefit in allergic airway diseases.[39] Butterbur, with the active ingredient petasin that exhibits antileukotriene and antihistamine activity, has shown some success but is not recommended for most patients.[17,40] Acupuncture is listed as an optional therapy in the latest guidelines, but high-quality evidence supporting the intervention is not available.[1]

Implement the Plan

The two primary pharmacotherapy options for the treatment of allergic rhinitis in adults and children are antihistamines and intranasal steroids. Patient preference should play a role when selecting between these two options. While limited evidence supports intranasal steroids over antihistamines, some patients may prefer simple oral therapy. Either choice requires clear patient counseling to ensure appropriate timing of therapy and expectations of effect.

For patients (both adults and children) who are not immunocompromised, have a high likelihood for adherence, and have adequate insurance and/or financial resources, subcutaneous specific immunotherapy is an excellent choice for treatment of seasonal allergic rhinitis and allergic rhinitis secondary to house dust mites. In some children, immunotherapy may prevent development of asthma. Sublingual immunotherapy may be beneficial to patients who are sensitive only to ragweed or certain types of grasses.

For patients experiencing an exacerbation of nasal congestion as part of their allergic rhinitis picture, decongestants can be used for short term.

Leukotriene receptor antagonists should not be recommended as primary therapy for allergic rhinitis; however, patients with allergic rhinitis and asthma may benefit from this therapy.

Cromolyn is another alternative that is effective, but many patients may find its frequent daily dosing (up to six times daily) difficult.

Follow-up: Monitoring and Evaluating Outcomes

More supportive evidence is needed to determine which patients, if any, would benefit from the other alternative options mentioned earlier.

With allergic rhinitis, major outcomes include the effect of the disease on a patient's life, the efficacy and tolerability of treatment, and patient satisfaction. Consideration must be given to how the condition is affecting the patient's job or school performance, family and social interactions, and other aspects of quality of life. Drug therapy should prevent or minimize symptoms with few adverse effects. The patient should not have difficulty obtaining needed medication for financial or other reasons. Patients should be questioned about their satisfaction with the management of their allergic rhinitis. The management should result in minimal disruption to their lives.

A drug monitoring summary is shown in Table e14-8. Intranasal and ophthalmic antihistamines may be helpful for specific symptoms not relieved by first-line choices. An intranasal anticholinergic such as ipratropium is specifically useful for rhinorrhea.

TABLE e14-8

Monitoring of Medications for Allergic Rhinitis

Drug	Adverse Reaction	Monitoring Parameter	Comments
• Antihistamines	• Drowsiness • Gastrointestinal effects • Anticholinergic effects	• Caution patient about the potential for drowsiness, even with nonsedating and intranasal products • Counsel patient to take with a meal or full glass of water • Watch for dry mouth and difficulty with urination. Caution patient about other medications with anticholinergic effects	• Do not mix with alcohol or other CNS depressants • Switching to an antihistamine with less anticholinergic effects may be necessary
• Decongestants ◦ Topical ◦ Systemic	• Rebound vasodilation • Local irritation • Hypertension • CNS stimulation	• Watch for decreased response to topical agent • Watching for burning, stinging, sneezing, and dryness of mucosa • If used in a patient with hypertension, monitor blood pressure regularly and discontinue if the pressure increases • Usually mild but discuss with	• Avoid prolonged use (>3-5 days) • Self-limiting due to short-term use. May try nasal saline for dryness • Usually not an issue for patients without preexisting hypertension. • Use lowest effective dose

		patient	
- Nasal steroids	- Local effects such as sneezing, stinging, and epistaxis	- These effects may vary among products.	

- Other intranasal agents
  - Cromolyn
  - Ipratropium
	- Local effects such as sneezing, burning, or coughing
	- Headache, nosebleeds, and nasal dryness
		- Usually mild but tell patient to report bothersome symptoms
		- Usually mild, tell patient to report bothersome symptoms
			- If patient cannot tolerate local reactions, choose an alternative agent
			- If patient cannot tolerate local reactions, choose an alternative agent

- Montelukast	- Behavioral changes	- Monitor for mood and behavioral changes including suicidal ideation	- Rare but should be monitored
- Immunotherapy, SC - Immunotherapy, SL	- Local reactions - Allergic reactions - Pruritis of ear, oral itching, mouth edema, throat irritation	- Watch for induration or swelling at site of injection - Monitor for signs of anaphylaxis - Caution patient about these reactions as they are fairly common	- Anaphylaxis rare, but should only be given under direct medical supervision with epinephrine available - First dose giving in physician's office so patient can be observed for 30 minutes. Prescription must be accompanied by a prescription for an epinephrine autoinjector.

Methods for assessing patient-reported outcomes and health-related quality of life in clinical trials related to allergy have been recommended.[41] These tools go beyond measuring improvement in symptoms and include such items as sleep quality, nonallergic symptoms (eg, fatigue, poor concentration, and others), emotions, and participation in a variety of activities. How well each of the current treatment modalities performs and how they compare in improving patient outcomes remain to be determined.

Clinicians caring for allergic rhinitis patients should develop a comprehensive pharmaceutical care plan that addresses several areas. Discuss and agree on therapeutic end points for allergic rhinitis, including the patient's acceptable level of symptom relief, onset of symptom relief expectations, and seasonal starts and stops. Discuss adverse drug reaction self-monitoring and prevention based on treatment selection. Assess patient attitude toward adherence to and persistence with oral, ocular, intranasal, or immunologic therapies. Ensure proper matching of treatment to symptoms and intervene with the prescriber if necessary. Conduct seasonal or annual review with patient.

The therapeutic goal for all patients with allergic rhinitis is to minimize or prevent symptoms. Evaluation of success is accomplished primarily through the discussions with the patient, in whom both relief of symptoms and tolerance of drug therapy must be discussed.

CONCLUSION

Allergic rhinitis is a common disease with symptoms ranging from mild to severe. If avoidance measures are unsuccessful, allergic rhinitis should be treated to improve quality of life and prevent long-term complications. Timing of treating is essential. Treatment regimens should be individualized based on patient symptoms and response. Care should be taken to correctly identify allergy as the cause of the patient's rhinitis before committing them to chronic treatment.

SELF-ASSESSMENT QUESTIONS

1. Sensitization to inhaled allergens in the United States is estimated to be

A. 5%

B. 13% in children and 14% in adults

C. 15%-30 %

D. 25%-50%

E. >50%

2. Persistent allergic rhinitis is a year-round disease that can be caused by which of the following?

A. Dust mites

B. Oak tree pollen

C. Animal dander

D. Ragweed pollen

E. Both A and C

3. Inflammatory mediators produce all of the following in the nose except:

A. Decreased vascular permeability

B. Rhinorrhea

C. Nasal congestion

D. Sneezing

E. Vasodilation

4. Which of the following are possible complications of allergic rhinitis?

A. Dental malocclusion and orthodontic problems

B. Poor work or school performance

C. Allergic shiners resulting from venous pooling under the eyes

D. All of the above

E. Only A and C

5. Prior to allergen skin testing, which of the following drugs should be stopped for at least 10 days?

A. Olopatadine

B. Pseudoephedrine

C. Intranasal fluticasone

D. Cetirizine

E. All of the above

6. Which of the statements regarding nonpharmacologic management of allergic rhinitis is true?

A. Avoidance of the offending allergens is effective in most patients.

B. Increasing humidity in the home above 50% helps with reactions to indoor allergens.

C. If removal of a pet is unacceptable, keeping the pet out of the patient’s bedroom and washing the pet weekly may be beneficial.

D. Saline washes for nasal passages and sinuses are almost never helpful.

E. Smoking in the house is acceptable but smoking in the car with the patient should be avoided

7. Which of the following statements is true regarding antihistamines?

A. An antihistamine is more effective at reversing allergic rhinitis symptoms than preventing them.

B. For most patients, peripherally selective agents are recommended over nonselective agents because they do less sedation.

C. There is no need to counsel patients on the use of antihistamines because most are available OTC.

D. A and B are true.

E. None of the above are true.

8. Which of the following have a high level of evidence for their effectiveness for initial treatment of allergic rhinitis?

A. Nasal steroids.

B. Oral leukotriene receptor antagonists.

C. A nasal steroid combined with an oral antihistamine.

D. Avoidance.

E. A, C, and D all have a high level of evidence to support their use.

9. Patients experiencing allergic conjunctivitis while receiving nasal steroids may benefit from having what drug added to their regimen?

A. Azelastine

B. Cromolyn sodium

C. Levocarbastine

D. An intranasal decongestant

E. A systemic decongestant

10. Rhinitis medicamentosa may be a complication of which of the following drugs if used for more than 3 days:

A. Diphenhydramine

B. Sublingual immunotherapy

C. Fluticasone

D. Oxymetolazone

E. Loratadine

11. Intranasal fluticasone:

A. Provides immediate relief of allergic rhinitis symptoms

B. Does not require patient counseling because it is available OTC.

C. May cause growth suppression in children and this effect outweighs the clinical benefit so this agent is not recommended in children under the age of 12.

D. Is likely to cause local infections with *Candida albicans;* therefore should not be used in patients over the age of 65.

E. Has had no significant association with hypo-pituitary axis suppression.

12. Which of the following statements are false regarding cromolyn sodium?

A. It has no direct antihistaminic properties.

B. It has no direct anticholinergic properties.

C. It has no anti-inflammatory properties.

D. Patients should be instructed to clear nasal passages before administration.

E. For seasonal allergic rhinitis, it should be started just before the offending allergen's season and continued throughout the season.

13. The following statements about subcutaneous immunotherapy are true except:

A. Candidates should have a history of symptoms controlled by antihistamines and/or nasal steroids.

B. It is a slow gradual process.

C. Effectiveness has been demonstrated in clinical trials using pollen extracts.

D. Three years of immunotherapy may be sufficient to give some patients lasting benefits.

14. Which of the following is true regarding sublingual immunotherapy

A. The tablets are dissolved under the tongue and swallowed immediately.

B. Prescriptions may be accompanied with a prescription for an epinephrine pen only if the physician considers the patient high risk.

C. For pollen allergens, they must be given year round to maintain effect.

D. The first dose must be given in the physician's office where the patient is observed for 30 minutes.

15. Key elements of evaluation of the therapeutic outcome of a patient with allergic rhinitis include:

A. The effect of the disease on the patient's life

B. The efficacy of the treatment regimen

C. The tolerability of the treatment regimen

D. The patient's satisfaction of the treatment regimen

E. All of the above

SELF-ASSESSMENT QUESTION-ANSWERS

1. **C.** Allergic rhinitis is one of the most common diseases affecting adults and children in the United States. While prevalence rates using physician-confirmed diagnosis are 13% in children and 14% in adults, actual sensitization to inhaled allergens is estimated to be higher.

2. **E.** Persistent allergic rhinitis is caused by allergens that are present year round, such as house dust mites, animal dander, cockroaches, and certain mold types. Pollens are released in the fall or spring.

3. **A.** A variety of mediators such as histamine, kinins, leukotrienes, and others cause *increased* vascular permeability.

4. **D.** Untreated allergic rhinitis can lead to complications that seem unrelated to typical symptoms of runny and stuffy nose, sneezing, and pruritic eyes. These symptoms may disturb sleep resulting in fatigue and poor work or school performance. Mouth breathing due to the chronic nasal congestion can lead to orthodontic problems. Chronic nasal congestion can also lead to venous pooling and dark circles under the eyes.

5. **D.** Any oral antihistamine the patient is taking should be stopped at least 10 days prior to allergen skin testing as they can decrease the sensitivity of the test by blocking or decreasing the skin reaction (positive result).

6. **C.** Nonpharmacologic approaches to treating allergic rhinitis are difficult and are rarely effective alone (see Table e14-3) for potential options. Most patients will not want to get rid of their pet. Keeping the pet out of the patient's bedroom, off carpet and upholstered furniture, and washing the pet weekly may be difficult but can be beneficial.

7. **B.** Antihistamines are much more effective in preventing allergic rhinitis symptoms; therefore, counseling patients about taking them before

allergen exposure is helpful. Also, patients must be fully aware of potential adverse effects. Peripherally selective antihistamines are less sedating and are recommended as first line.

8. **A.** The strongest evidence for initial treatment of allergic rhinitis exists for intranasal steroids alone or peripherally selective antihistamines alone.

9. **C.** Nasal steroids have little effect on ocular symptoms of allergic rhinitis since they act primarily in the nasal passages. Adding an ocular antihistamine may prove beneficial.

10. **D.** Intranasal decongestants, such as oxymetazoline, if used for more than 3 days can cause rebound vasodilation resulting in even more severe nasal congestion than the patient was initially experiencing. This leads to higher and more frequent doses that may provide some temporary relief, but the rebound congestion worsens.

11. **E.** Intranasal steroids are minimally absorbed so the worrisome effects of systemic steroids are not a concern with local use. These agents take over a week to be effective and are more effective if taken just prior to the start of allergy season, so patients should be counseled about these points and on the proper administration technique.

12. **E.** To be effective, cromolyn must be started just before the usual start of the allergen's season and continued throughout the season. If not, it may take 2 to 4 weeks to provide any relief.

13. **A.** The best candidates for immunotherapy are those that have not responded to other pharmacotherapeutic options.

14. **D.** With sublingual immunotherapy, the first dose must be given in the physician's office where the patient can be observed for at least 30 minutes. The risk of anaphylaxis is low but care must be taken to see how the patient will respond since anaphylaxis is a life-threatening condition. For this reason, an autoinjectable epinephrine must be provided with the prescription for the sublingual product.

15. **E.** All of these items are important and must be considered.

Chapter e15: Oral Health and Systemic Conditions

Lisa M. Palmisano; Jennifer L. Mazan

KEY CONCEPTS

KEY CONCEPTS

① Oral health is a growing global concern because of its effect on quality of life, morbidity, and mortality.

② Dental caries in children can significantly impair their overall health status.

③ Periodontal disease in older populations may contribute to progression of noncommunicable diseases (ie, diabetes).

④ Poor oral health conditions are associated with increased mortality risk.

⑤ Medications taken for various conditions may contribute to significant oral adverse effects that result in worsening oral health outcomes.

⑥ Diabetes and periodontal disease have a bidirectional relationship on glycemic control and periodontal disease progression.

⑦ Medications used for various cardiovascular disease conditions have significant oral adverse effects that result in reduced oral health outcomes and patient quality of life.

⑧ Patients with respiratory conditions and who require inhaler medications are at an increased risk of dental caries, periodontal disease, dental erosion, and oral candidiasis.

⑨ Poor oral health in patients with psychiatric disorders may result from various contributing factors such as medication-related side effects, existing co-morbidities, and barriers to accessing dental care.

⑩ Tobacco and substance use disorders are significant contributors to poor oral health consequences, particularly in those with other psychiatric conditions.

⑪ Oral health disparities are noted across patients' lifespans as a result of access to dental coverage, income, education, and race/ethnicity.

⑫ National and local initiatives have been created to increase awareness, education, and access for oral healthcare for all Americans.

⑬ Nondental healthcare professionals, including pharmacists, can play an integral role in educating patients on oral health as it pertains to oral health diseases, systemic diseases, and medication-related adverse effects.

BEYOND THE BOOK

BEYOND THE BOOK

Test your baseline knowledge on various oral health topics using the online short quizzes below:

General website (http://www.mouthhealthy.org/en/az-topics/quiz-time)

Specific short oral health quizzes:

1. What causes dry mouth?
2. Is all tobacco bad?
3. Kids' dental health
4. Teen dental health
5. Adults under 40 dental health
6. Adults 40 to 60 dental health
7. Adults over 60 dental health

INTRODUCTION

① Oral health encompasses the oral tissues, dentition, mastication ability, and tongue movement along in the absence of chronic oral-facial pain, cancers, oral lesions, or other oral conditions or diseases that affect the oral, dental, or craniofacial tissues.[1] Poor oral health can result in physical oral dysfunction, malnutrition, sociopsychological impairment, cognitive decline, and a reduced overall quality of life.[2,3] The global concern of oral health is a result of the disparities in accessing providers as well as the growing evidence that it is a modifiable risk factor for chronic systemic conditions and oral disease.[1–4] The manifestation of oral symptoms such as xerostomia, candida infections, and ulcerations are examples of potential indicators of chronic conditions such as diabetes, cardiovascular disease (CVD), autoimmune disease, and others.[3,5] Furthermore, medical condition(s) and medication treatment can negatively affect a person's oral health. The World Health Organization, US Surgeon General, and other healthcare organizations have emphasized the call to action for improvement of oral health care.[1,6–8]

GENERAL ORAL HEALTH CONDITIONS AND OUTCOMES

Oral health conditions can affect surface tissues and dentition, as well as the craniofacial tissues such as the salivary glands or jawbones. Dental caries and periodontal disease are specific conditions that are prevalent across the population.[1] Risk factors for developing these include tobacco use, excessive alcohol, illicit drug use, diabetes, xerostomia, and Downs's syndrome.[5] Those who are unable to access or pay for dental care and those unable to provide appropriate self-oral care are also at risk of developing these conditions.[5] Dental caries and periodontal disease are discussed in further detail below as they relate to other systemic conditions (see Fig. e15-1).

FIGURE e15-1

Dental caries (top image) and periodontal disease (bottom image). The top image shows a case of dental caries. The bottom image shows a case of periodontal disease. There are arrows pointing to the space between the teeth on the bottom jaw. *(Reproduced, with permission, from Durso SC, Yellowitz JA. Atlas of Oral Manifestations of Disease. In: Jameson J, Fauci AS, Kasper DL, et al., eds. Harrison's Principles of Internal Medicine. 20th ed. New York, NY: McGraw-Hill; 2018.)*[5]

Dental Caries

Dental caries result from a complex process in which biofilms form on the teeth in the presence of sugars[2,5,8] (see Fig. e15-1). Increased acid formation from microorganisms in the biofilms causes demineralization of the tooth resulting in cavity development. Left untreated, dental caries may further affect the tooth center, or dental pulp, which is highly vascularized with nerves and connective tissue leading to tooth loss. Bacteria from the oral cavity can enter circulation through the damaged dental pulp resulting in infection and potentially sepsis.[2]

② The proportion of children ages 5 to 19 in the United States with untreated cavities is about 13.2%.[9] Children with untreated caries can experience pain, decreased ability to chew food, increased school absences, difficulty concentrating, overall reduced quality of life, and poor academic success.[8,10,11] More than 90% of adults in the United States have had a cavity, and 1 in 4 have untreated cavities.[8] Dental caries may lead to tooth loss and instability, which affects chewing ability and reduces food choices. This can impair the nutritional status of a patient, leading to further deterioration of their oral and overall health.[3,8]

Treatment of dental caries depends on the involvement of the tooth structure, particularly the tooth pulp.[5] Infected tissue can be removed and restored with silver amalgam, glass ionomer, gold, or other fillings. If the pulp is infected and damage is irreversible, invasive dental procedures such as extractions or root canals are necessary.

Periodontal Disease

Periodontal disease, or periodontitis, is a chronic condition resulting from progressive inflammation of the gums (gingivitis) that results in a loss of soft tissue (gums) and bone, ultimately leading to tooth mobility and/or loss.[2,3,5,8,12,13] See Fig. e15-2 for a comparison of the periodontal anatomy in healthy tissues and periodontal disease.[13] Signs of gum disease are redness, swelling, pus, increased bleeding from the gums, increased space between teeth, tartar build up, and/or or tooth loss[2,8,13,14] (see Fig. e15-1). Periodontal disease is classified as stage I through IV based on the level of severity (ie, clinical attachment loss, radiographic bone loss, and tooth loss), complexity (ie, probing), and extent and distribution (ie, localized or generalized).[14] Additionally, there is a grading system to assess the rate of periodontitis progression. It is well documented that periodontal disease is more severe in those with diabetes, tobacco use, weakened immune systems, lower socio-economic status, Hispanic, and non-Hispanic Black populations.[4,13–15]

FIGURE e15-2

Comparison of healthy and periodontal disease anatomy. The image shows the difference between a healthy tooth and a periodontal disease infected tooth. An anatomical diagram of the tooth is shown. The tooth is split into half. The left side is labeled as Healthy and the right side is labeled as Periodontal Disease. A pair of tweezers is holding the tooth. There are two parts labeled in the Healthy part. They are Healthy Gums and Healthy Bone Level. There are two parts labeled in the Periodontal Disease part. They are Plaque Tartar, Pocket, and Reduced Bone Level. *(Reproduced, with permission, from Usatine RP, Smith MA, Mayeaux EJ Jr, Chumley HS, eds. The Color Atlas of Family Medicine. 3rd ed. New York, NY: McGraw-Hill; 2019.)*[13]

Morbidity/Mortality Outcomes of Poor Oral Health

Poor oral health has been linked to a reduced quality of life and increased risk of morbidity and mortality.[3,5] Poor dentition has a negative impact on patients' diet, impairing self-esteem, decreasing daily life activities, and reducing overall well-being. It has also been shown to increase the risk of chronic kidney disease, dementia, sleep-disorder breathing, coronary heart disease, diabetes, and some cancers (eg, lung).[3,5,16,18] While the literature discusses the relationship between oral health and morbidity, most studies are observational in design and therefore do not support definitive cause–

effect relationships. However, the weight of the evidence strongly suggests relationships between oral disease and several systemic conditions, as discussed in the following sections of this chapter.

4 Poor oral health is directly related to an increased risk of mortality.[19–22] Edentulism (loss of all natural teeth because of disease or decay), dental caries, periodontal disease, and mastication dysfunction are shown to increase the risk of mortality. Poor oral dentition alters a person's ability to chew properly, leading to detrimental modifications in diet and malnutrition, which is related to overall mortality.[3,5,20,21] Having fewer teeth has been significantly correlated to increase overall mortality.[20,21] Poor oral health in combination with pre-existing conditions such as CVD,[20] cancer,[20] hemodialysis,[18] and/or cognitive impairment,[16] are associated with increased mortality. Conversely, there is an inverse relationship of denture use with mortality.[23] The highest overall mortality risk was found when more than three oral health issues were present.[24] See Table e15-1 pertaining to a summary of oral health factors known to affect mortality risk.[19–23]

TABLE e15-1

Oral Health Condition and Mortality Risk

Oral Health Condition	Mortality Outcome
Dental caries	↑
Mastication dysfunction	↑
Periodontal disease	↑
Tooth loss	↑
Dentures	↓

Data from References 19-23.

Medication-Related Orofacial Adverse Effects

5 Medications taken for various conditions can impact the health of the oral cavity and through various mechanisms.[25–30] Adverse drug events that affect the oral cavity can present within days, months, to years of medication initiation. Medications affect the salivary process (ie., xerostomia), soft (mucosal) tissue (ie, lichenoid reactions), and hard tissue (ie, dental caries). Additionally, other nonspecific oral adverse effects such as taste disorders and halitosis can occur. Details of these oral adverse effects are discussed throughout this chapter. See Table e15-2 pertaining to a summary of the orofacial regions and coinciding oral adverse effects.[25]

TABLE e15-2

Orofacial Structure Impacted and Oral Adverse Reactions

Orofacial Structure	**Oral Adverse Reaction(s)**	
Saliva and Salivary glands	• Salivary gland enlargement • Sialorrhea	• Xerostomia
Soft (mucosal) tissue	• Angioedema • Aphthae/ulcerations • Drug hypersensitivity syndrome • Gingival overgrowth • Lupus erythematosus-like syndrome	• Pemphigoid/pemphigus • Stevens Johnson Syndrome (SJS) • Toxic epidermal necrolysis (TEN)
Hard tissues	• Dental caries • Drug related osteonecrosis	• Dry Socket • Tooth discoloration
Non-specific conditions	• Bruxism • Dysgeusia (taste disturbance)	• Halitosis • Infection

Data from Reference 25.

DIABETES MELLITUS AND ORAL HEALTH

General Oral Health Concerns

Patients with diabetes and/or poor glycemic control have increased risk of various oral complications.[15,31–34] As a result of immune and inflammation dysregulation, patients with chronic hyperglycemia are more susceptible to taste dysfunction, dental caries, tooth loss, delayed wound healing, infections (ie, candidiasis), development of lichen planus, and periodontal disease. Lichen planus, from chronic inflammation, is a condition that affects the oral mucous membranes that appear as white patches; red, swollen tissues; or open sores.[31] Patients may experience oral burning sensations, pain, and discomfort. Additionally, patients may experience xerostomia due to dehydration causing salivary dysfunction, reduced blood flow to the salivary glands, and decreased production of saliva, all of which may increase the risk of opportunistic fungal infections like candidiasis.[31,32] Xerostomia may also be a result of medications taken. (See xerostomia section in "Oral Hygiene and Minor Oral Disorders," Chapter e16.)

Diabetes and Periodontal Disease

⑥ Diabetes and periodontal disease exhibit a bidirectional relationship, increasing the risk and severity of the other condition.[12,15,31,32,34,35] Overall, those with progressive periodontal disease, have a larger increase in glycosylated hemoglobin (A1c) compared with those without periodontal disease In patients with severe periodontal disease, the risk of developing diabetes was 33%, and the risk of periodontitis is about three times greater in patients with diabetes than in those without diabetes.[12,31,35] In the United States, two-thirds of those 65 years and older have coexisting diabetes and periodontal disease.[34] Evidence has shown that patients with diabetes who have periodontitis are at increased risk of diabetic nephropathy, cardiovascular events, and mortality.[12,15,34]

Poorly controlled diabetes or hyperglycemia can result in production of advanced glycosylation end products (AGEs), which can lead to dysregulated immune and inflammatory processes.[12,35] The AGEs promote inflammation and microbial exposure in oral tissues, in addition to tissue and bone breakdown, resulting in periodontal disease.[34,35] Periodontal infections have been linked to increased oxidative stress and cytokine production, which enhance insulin resistance, worsen glycemic control, and increase the risk of diabetic complications (eg, cardiovascular events).

Treatment of diabetes or periodontal disease functions bidirectionally such that an improvement in one condition also improves the other.[12,15,35] The onset of confirmed diabetes along with treatment to achieve optimal glycemic control can minimize development or progression of periodontal disease in patients with diabetes.[15] (See "Diabetes Mellitus," Chapter 94, for full review of diabetes and its management.) The treatment of periodontal disease significantly improves glycemic control in patients with diabetes.[17,34,35] Three months of periodontal treatment demonstrated a 0.27 to 1.03 reduction in A1c (2.9-11.2 mmol/mol).[17,34,35] If these results are sustained, a reduction in complications from diabetes may be noted. The relationship between periodontal disease and diabetes provides evidence that more education and preventive screenings are needed.

Patient Education on Oral Health and Diabetes

Emphasis for patient care with diabetes has been on the prevention of macrovascular and microvascular complications (see Chapter 94, "Diabetes Mellitus"). Overall, evidence shows that lowering the A1c by 1 percentage point (11 mmol/mol) can reduce microvascular complications by 35%, and a 0.2% (2.1 mmol/mol) reduction in A1c can reduce mortality by 10%.[17,36] The significant improvement in glycemic control through A1c reduction, in those who received periodontal treatment, reinforces the bimodal direction these two conditions have on patient outcomes, particularly with lowering micro/macro-vascular complications.[15,17,34] This emphasizes the need for further oral health education and screening in patients with diabetes as well as screening for diabetes in patients with periodontal disease.

Since most nondental health professionals receive little training on the link between diabetes and oral health, this connection is not routinely discussed.[37] Education on oral health in this population needs to be further stressed, given the significant link between diabetes and oral health conditions, particularly periodontitis. Patients with diabetes need more education on the importance of regular professional oral checkups and daily hygiene; all health professionals should be prepared to refer patients with diabetes for oral healthcare.[38]

Health professionals, including pharmacists, should be educated on the relationship between diabetes and oral health to provide necessary counseling and recommendations. For instance, a patient's anti-diabetic medications can cause vomiting, and if this persist through treatment, dental erosion can result.[39] Metformin produces a metallic taste in 1% to 5% of patients during therapy initiation; this dissipates over time.[40] thiazolidinediones Oral mucosal changes, such as lichenoid reactions is noted with sulfonylureas, and drug induced bullous pemphigoid is associated with dipeptidyl peptidase IV inhibitors.[28] Drug-induced bullous pemphigoid is a variation of the autoimmune acquired reaction that results in blistering and ulceration, and once the drug is discontinued, the reaction resolves.[28] See Table e15-3 for oral adverse effects of antidiabetic medication classes.[25,26,28,30,41]

TABLE e15-3

Oral Side Effects of Antidiabetic Medication Classes

Medication Class	Examples of Oral Side Effects[a]
Biguanide	Dysgeusia, lichenoid reactions, vomiting
Sulfonylureas	Lichenoid reactions
DPP-IV inhibitors	Pemphigoid, vomiting
GLP-1 agonists	Dysgeusia, vomiting
Amylin	Vomiting
Insulin	Salivary gland pain/swelling

DPP-IV, dipeptidyl peptidase – IV; GLP-1, glucagon-like peptide-1

[a] Oral side effects may be specific to individual medications in that class and/or incidence of side effects may vary.

Data from References 25,26,28,30,41.

Another important counseling point is to refer patients with diabetes to an oral health professional for care and evaluation for periodontal disease.[15,32,33,35,42] Educating the patient to self-evaluate their oral health and to monitor for signs and symptoms of worsening oral health status is also recommended.[15,32,35] Patients should be encouraged to discuss their experiences of hypoglycemia with the oral health professionals at each visit in case episodes occur during treatments; this is especially important for those who are hypoglycemic unaware (not exhibiting typical signs of hypoglycemia during rapid drops in blood glucose levels). Depending on the dental practitioners' access to glucometers, patients can bring their glucometers to the dental visit to allow chairside blood glucose screening to minimize the risk of hypoglycemia during a dental procedure.

Pharmacists and other nondental health professionals should provide education and counseling to patients with diabetes to help enhance the understanding and importance of oral health and diabetes. See Table e15-4 for a summary of education points to consider when discussing diabetes and/or medications with patients with this disease.[15,32,34,42]

TABLE e15-4

Patient Education Points for Diabetes

Medication/Condition-Related Education	Dental Specific Recommendations
1. Educate on medication oral side effects (if applicable) 2. Counsel on the importance of dental care and risk/symptoms of periodontal disease ◦ Symptoms: gum bleeding, swelling, loose teeth, increased space between teeth 3. Manage xerostomia[a] ◦ Increase water consumption ◦ Sugar-free chewing gum ◦ Saliva substitutes	1. Regular dental appointments (at least every 6 months) ◦ Morning appointments are best to minimize hypoglycemia ◦ Consume well-balanced meal before a dental visit to minimize hypoglycemia 2. Depending on duration dental procedure, modifications to diabetic medication administration may be considered ◦ Discuss medication administration with physician.

[a] See xerostomia section in Chapter e16, "Oral Hygiene and Minor Oral Disorders."

Data from References 15,32,34,42.

CARDIOVASCULAR DISEASE AND ORAL HEALTH

Cardiovascular disease is the leading cause of death in the United States.[43] Risk factors associated with CVD includes but are not limited to smoking, hypertension, atherosclerotic disease, diabetes, and metabolic disorders (eg, obesity).[43–45] These risk factors are hypothesized to have strong associations with periodontal disease. Conversely, one could argue that periodontitis could be a CVD risk factor itself.[44,45] Medications used to treat various cardiovascular conditions often have significant adverse effects on the orofacial structures. Antihypertensive, antiarrhythmic, antiplatelets, oral anticoagulants, and antilipemic agents (ie, statins) are common classes of medications with concerning oral health side effects.[25–28,30]

Cardiovascular Disease and Periodontal Disease

There is growing evidence that periodontal disease is a potential risk factor for the development of CVD.[44–46] Systematic reviews and meta-analysis indicate an approximate 3.5-fold increased risk of CVD in those with periodontal disease, and an approximate 30% increase risk of acute CVD events.[45] Risk factors of CVD as mentioned above, when not controlled and associated with periodontal disease, have been linked to an increased risk of major adverse cardiovascular events (MACEs), stroke, and mortality.[44,45]

The presence of infection and inflammation secondary to periodontal disease have been identified as plausible mediators of progressing CVD risk, particularly through atherosclerotic progression.[44,45] Periopathogens (ie, *Porphyromonas gingivalis*) have been found in atherosclerotic plaques; these play a role in inducing inflammatory responses.[14,21,49,50] Secreted pro-inflammatory cytokines associated with periodontal disease may stimulate other host factors, such as fibrinogen and C-reactive protein (CRP), that further promotes the development of atherosclerotic plaque, increases arterial thickness, and/or alters endothelial function. The dysregulated host inflammatory and immune response to periodontitis can affect the atherosclerotic plaque formation and/or cause plaque instability, which may result in a cardiovascular event or potentially death. By treating the periodontal condition, the inflammatory and immune mediators can decrease, which is believed to reduce cardiovascular risk. Although evidence shows a potential cause–effect between periodontitis and CVD, there are limited data regarding whether treatment of periodontal disease can prevent cardiovascular events.[12,44,45] Further research is needed to establish a causal association.

Cardiovascular Medications and Oral Health Effects

⑦ The adverse oral effects of cardiovascular (CV) medications affect all structures of the orofacial region as well as the patient's quality of life. See Table e15-2 for a review of the orofacial structure and the defined oral adverse effects.[25] Oral side effects of CV medications include but are not limited to xerostomia, angioedema, aphthae, lichenoid eruptions, reactions, pemphigus/pemphigoids, lupus-like reactions, gingival overgrowth, and dysgeusia (taste disturbance). See Table e15-5 that list specific adverse oral effects of medication classes used for CVD management.[25-30,41]

TABLE e15-5

Oral Side Effects of Cardiovascular Medication Classes

Medication Class	Examples of Oral Side Effects[a]
Alpha-adrenergic blockers	Xerostomia
Beta-adrenergic blockers	Aphthae/oral ulceration, lichenoid reaction, pemphigoid, xerostomia
ACE inhibitors	Angioedema, aphthae/oral ulcerations, dysgeusia, lichenoid reaction, pemphigoid, xerostomia
ARBs	Angioedema, aphthae/oral ulcerations, dysgeusia
Class I antiarrhythmics (ie, sodium channel blockers)	Dysgeusia, vomiting, xerostomia Lupus erythematosus like reactions (quinidine, procainamide)
Class III antiarrhythmics (ie, potassium channel blockers)	Dysgeusia, oral mucosal pigmentation changes, xerostomia
CCBs	Angioedema, dysgeusia, gingival overgrowth, pemphigus, xerostomia
Diuretics	Angioedema, dysgeusia, lichenoid reactions, pemphigoid, SJS, TEN, xerostomia
Peripheral vasodilators	Lupus erythematosus like reactions (hydralazine)
HMG-CoA reductase inhibitors	Angioedema, lichenoid reactions, SJS, TEN
Antiplatelets	Angioedema, bleeding, dysgeusia, lichenoid reactions
Oral anticoagulants	Bleeding

ACE, angiotensin converting enzyme; ARBs, angiotensin II receptor blockers; CCBs, calcium channel blockers; HMG-CoA, β-Hydroxy β-methylglutaryl-CoA; SJS, Stevens Johnson Syndrome; TEN, toxic epidermal necrolysis

[a] Oral side effects may be specific to individual medications in that class and/or incidence of side effects may vary.

Data from References 25–30,41.

Saliva/Salivary Gland Reactions

Xerostomia or dry mouth can occur with various CVD medication classes. Although several mechanisms may account for this effect, it is thought to result from the anticholinergic action on muscarinic receptors, which reduces neurotransmission to the salivary glands, causing hyposalivation, and dry mouth.[25–27] Xerostomia has shown to increase the risk of dental caries, oral infections (ie, candidiasis), and taste disturbances as well as worsen periodontitis.[25,27,29,30] Several classes of CVD medications produce xerostomia, including alpha-adrenergic blockers, angiotensin-converting enzyme (ACE) inhibitors, beta-adrenergic blockers, class I anti-arrhythmics (eg, quinidine), calcium channel blockers (CCBs), and diuretics.[25–27,30] (See xerostomia section in Oral Hygiene and Minor Oral Disorders, **Chapter e16**.)

Soft Tissues: Oral Mucosa and Cutaneous Reactions

Angioedema, lichenoid reactions, pemphigus/pemphigoids, lupus-like reactions, and gingival overgrowth are examples of adverse effects of CV medications on the soft tissue of the oral mucosa and cutaneous structures. Drug-induced angioedema involves a sudden onset of swelling in the orofacial region and lips that can be life-threatening when the airway becomes compromised.[25,26,30] It typically presents within the first 3 months of treatment initiation.[30] CV medications known to result in angioedema are ACE inhibitors, angiotensin II receptor blockers (ARBs), CCBs, antiplatelet agents (ie, clopidogrel), and statins.[25,26,30]

Lichenoid reactions are clinically and histologically difficult to differentiate from idiopathic lichen planus.[25,26,28,30] The mechanism of drug-induced lichenoid reactions is not well defined. An immune-mediated reaction is thought to result in destruction of the epithelium and present as white striations or papules on the buccal mucosa, gingiva, and tongue. This reaction is often present in a unilateral, single oral ulcer that is unlike lichen planus, which presents in a bilateral, symmetrical manner.[25,28,30] Onset of lichenoid reactions may appear variably with treatment initiation from weeks to a year or more, and this side effect may persist for several months after discontinuing the offending medication.[25,30] Offending medications are ACE inhibitors, beta-adrenergic blockers, diuretics, and statins.[25,26,28,30]

Drug-induced pemiphigus is a rare drug-induced autoimmune reaction, that appears as bullae, which present initially as blisters that progress to ulcerations.[25,28] It is a variant of bullous pemphigoid, but often appears in younger populations; eliminating the triggering drug allows the ulcer to heal. Drugs containing thiol and sulfonamide derivatives are believed to facilitate the development of drug-induced pemphigus/pemphigoid reactions. CV medications such as ACE inhibitors, specifically captopril and enalapril, diuretics (ie, furosemide), beta-adrenergic blockers, and CCBs can induce these reactions.[25,28]

Drug-induced lupus-like reactions have been documented with many medications, including the CV medications hydralazine, quinidine, and procainamide.[25,28] The exact mechanism of drug-induced lupus is not fully understood but is believed to be an immune response provoked by the medications. The reaction may appear as oral ulcerations and/or lichenoid planus, along with other lupus-like symptoms (ie, malar rash); it resolves upon discontinuation of the offending agent.[25,28]

CCBs are known to cause gingival overgrowth.[25–27,] These agents are thought to reduce the collagenase activity that leads to an increase in collagen within the gum tissues, resulting in enlargement of gingiva.[26,29] The amount of plaque present is an independent risk factor for gingival enlargement. Men are three times more likely than women to develop such changes. Diltiazem and nifedipine have the highest incidences of gingival overgrowth (5% to 20% and 6% to 15%, respectively); followed by verapamil (approximately 5%); and then amlodipine (2% to 3%).[29] Onset may occur within the first three months of treatment initiation. Treatment for gingival overgrowth may require discontinuation of the medication, decreased dosing, switching the agent to one with a lower incidence, and/or more frequent dental visits and procedures. Reduction to gingival baseline may take up to 1 year.[29]

General Oral Health Reactions

Dysgeusia or taste disturbance is a known oral adverse effect from CV medications.[25,27,30] Although the mechanism of how this occurs is not clearly defined, the drugs or their metabolites can affect receptors or messenger centers that result in altered taste. Dysgeusia is noted with ACE inhibitors and CCBs, resulting in a bitter or metallic taste. Taste disturbances may be worsened with tobacco and alcohol use and can further exacerbate other oral health problems such as xerostomia or dental caries.[30] The best management is to discontinue the medication; resolution may take up to 4 months.[25]

Patient Education on Oral Health and Cardiovascular Disease

Discussion of oral health with patients who have CVD or are taking medications for CVD should be emphasized.[29,44,45,47] Periodontal disease education and evaluation should be recommended for all patients with CVD or those with risk factors (ie, increased inflammatory markers such as CRP).[44,45] In the short term, treating periodontal conditions may decrease systemic inflammatory markers, improve endothelial function, and enhance a patient's overall oral health. Although not definitively associated, improvement in oral health may minimize systemic progression of CVD.[44,45]

Pharmacists in any setting can be active patient educators about the relationship among oral health, CVD, and medications[47,48] (see Table e15-6). All patients should have routine dental care, but this is especially important to emphasize to those with CVD and taking medications with adverse oral effects. For instance, in patients taking diuretics, xerostomia may be noted. When routine dental care is provided, the dental provider may discuss recommendations for the xerostomia to minimize the development of caries and oral infections such as candidiasis.[25,27,30] Additionally, for those patients taking CCBs, gingival overgrowth can occur, most often in the first three months of treatment.[25,27,29,30] If left untreated, gingivitis can affect mastication, aesthetics, breath odor, and speech. By encouraging routine dental care and educating the patient appropriately, identification of oral side effects from CV-related medication may occur earlier which will allow for the discussion of alternative treatment recommendations with the prescriber.[29,30]

TABLE e15-6

Patient Education Points for Cardiovascular Disease

Medication- or Condition-Related Education	Dental Specific Recommendations
1. Educate on medication oral side effects (if applicable) 2. Counsel on the importance of dental care and risk/symptoms of periodontal disease ○ Symptoms: gum bleeding, swelling, loose teeth, increased space between teeth 3. Manage xerostomia[a] ○ Increase water consumption ○ Sugar-free chewing gum ○ Saliva substitutes	1. Regular dental appointments (at least every 6 months) 2. Depending on duration dental procedure, modifications to CVD medication administration (ie, antiplatelet or anticoagulant) may be considered ○ Discuss with physician prior to any dental visit or procedure 3. Elective dental procedures are to be deferred for at least 30 days following any CVD event (eg, myocardial infarction)

[a]See xerostomia section in Chapter e16, "Oral Hygiene and Minor Oral Disorders."

Data from References 47,48.

RESPIRATORY DISORDERS AND ORAL HEALTH

Oral Health Concerns

8 The link between oral health and respiratory diseases is well established. The oral cavity may serve as a reservoir for potential pathogens that can be deposited into the lungs, leading to various types of infections.[49] Patients with respiratory diseases such as asthma and chronic obstructive pulmonary disease (COPD) are more likely to be at risk for certain oral health problems such as dental caries, erosion, periodontal disease, and candidiasis.[48–51]

Respiratory Conditions and Dental Caries

Dental caries are more notable in patients with respiratory disorders.[49–51] Patients with COPD are more likely to have poor oral hygiene and worse oral care habits than those without, which results in more dental plaque and caries.[49] In those with asthma, particularly children, numerous studies support that the risk of dental caries is almost two times greater in those with asthma compared with those without asthma.[50,51] Contributing factors that correlate to increased development in caries are thought to develop from biological etiologies such as result of salivary flow and composition changes, or from external factors such as medications or lifestyle. Medications, disease severity, and symptom duration are directly linked to an increased risk for dental caries.[49–51] However, other studies revealed there was not an association between asthma and dental caries.[50,51] Such contradicting results may be the result of different formulations and delivery devices of medications, the level of fluoride protection, lifestyle choices, and asthma severity when the literature was reviewed.

Medications for respiratory conditions have the potential to cause xerostomia, preventing the natural ability of the mouth to rinse itself. This can lead to an increased growth of bacteria such as *Lactobacillus* species and *Streptococcus mutans*.[50] Inhalers with beta-2 agonist action have shown to cause a reduction in salivary flow, decreasing the pH in saliva and plaque, thereby inhibiting the natural buffering effect of the oral cavity. All of these factors contribute to the formation of dental caries.[50,51] Another contributing factor to dental caries may be the presence of lactose in some inhaled dry powder formulations. This in combination with the decrease in salivary flow can potentially lead to dental caries. Increased consumption of cariogenic foods (ie, sugary or acidic beverages) can also contribute to dental caries. Patients often use these to rinse away the taste of the medication or to soothe dry mouth.[50,51] Additionally, parents sometimes compensate by providing sugary treats for the child as a way to compensate for having the asthmatic condition.[51]

Dental Erosion

There is also evidence regarding increased enamel erosion in patients with inhaler use.[50,51] Risk factors such as mouth breathing, xerostomia, consumption of acidic/sweet beverages with low pH, and gastroesophageal reflux have been found to contribute to enamel erosion.[50] The threshold for tooth enamel demineralization occurs at a pH less than 5.5, and inhalers, particularly dry-powder, create an environment where the pH is less than the threshold in the oral cavity, resulting in dental erosion.[50,51] Consumption of sugary/acidic beverages can also contribute to a lower oral pH that enhances the demineralization of the tooth enamel. Additionally, beta-2 agonist inhaler use in asthmatics has been linked to increased gastroesophageal reflux leading to dental erosion.[48,50,51] Relaxation of the smooth muscle in the lower esophageal sphincter by beta-2 agonists, gastric acid to enter into the mouth. The repeated acid exposure increases the potential for dental erosion. Use of spacer devices, rinsing solutions with sodium bicarbonate, optimal oral self-care, and treating acid reflux in minimizing the risk dental erosions.[50,51]

Respiratory Conditions and Periodontal Disease

Periodontal disease has been associated with respiratory conditions.[49,50] Altered immune responses, that may result in aspiration of bacteria is one hypothesis explaining the link between respiratory conditions and periodontal disease. Pulmonary pathogens such as a *Hemophilus influenza* or *Pseudomonas aeruginosa* have been found harboring in the biofilms of dental plaque. Additionally, oral flora such as *Prevotella* have been found in bronchial microbiomes in patients with bronchitis, and in patients with COPD, *Streptococcus viridians* was found in the sputum.[49] Inflammatory proteins from periodontal disease may contribute to worsening respiratory symptoms, exacerbation of the condition, and destruction of lung tissue.[49,50] For instance, elevated tumor necrosis factor—alpha, found in periodontal disease has been increased in the sputum of COPD patients, and continues to increase during exacerbations. Metalloproteinases destroy oral connective tissue and enamel as well as lung parenchyma, which may be a contributing factor in the etiology of COPD, asthma, or other respiratory diseases development. Systemic inflammatory markers (ie, CRP) were also found to be elevated in those with respiratory conditions.

In patients with COPD, periodontal disease may be considered an independent risk factor.[49] Studies adjusted for confounding risk factors for COPD such as smoking, socioeconomic status, and poor oral hygiene, found that in those with periodontitis, the odds of developing COPD increased by approximately 45% to 60%.[49] Studies show that patients with COPD are more likely to have poorer oral health habits such as not brushing or flossing their teeth and having fewer dental visits per year compared to those without COPD, and as a result of poor oral hygiene, may be more prone to COPD exacerbations. Small trials have demonstrated that treatment of periodontal disease led to a reduction in COPD exacerbations, but larger trials are needed to confirm these results.[49]

Periodontal disease in patients with asthma, similar to the immune and inflammatory etiologies discussed above, may be heightened with the added presence of inhaler side effects (ie, xerostomia).[49–51] The effects of reduced salivary flow alters the natural oral composition, allowing for higher rates for calculus deposits, which may enhance development of gingivitis and periodontitis. Additionally, the use of inhaled corticosteroids (ICS) can lead to decreased bone density of the mandible over time which can impact the progression of periodontal disease. Using the lowest dose of ICS inhalers is important for the long-term management of asthma.[50]

Although these risk associations have been identified, no causal relationship has been defined between periodontal disease and these respiratory conditions. There is still more research needed to identify if periodontal disease treatment lessens the prevalence of the pulmonary conditions.[49,50]

Patient Education on Oral Health and Respiratory Disorders

Pharmacists need to educate their patients with respiratory conditions, such as asthma and COPD, about increased risks of developing oral health problems along with medication-related oral side effects. See Table e15-7 for full review of respiratory medication oral- related side effects.[26,29,30,41,50,51]

TABLE e15-7

Oral Side Effects of Respiratory Medication Classes

Medication Class	Examples of Oral Side Effects[a]
Beta-2 agonist inhalers	Dental caries, dysgeusia, gastroesophageal reflux, glossitis, oral candidiasis, throat irritation, xerostomia
Corticosteroid inhalers	Dental caries, dysgeusia, dyspepsia, oral candidiasis, throat irritation, xerostomia
Leukotriene inhibitors	Dyspepsia, toothache

[a] Oral side effects may be specific to individual medications in that class and/or incidence of side effects may vary.

Data from References 26,29,30,41,50,51.

Oral candidiasis is a well-known side effect of inhalers, predominantly from ICS inhalers. These inhalers play a central role in asthma management and significantly contribute to candidiasis infection. Overall immunosuppressive effects of these inhalers and the addition of lactose in many of the formulations contribute to growth, proliferation, and adhesion of *Candida* in the oral cavity.[50] Xerostomia, from other inhalers (ie, beta-2 agonist), can also predispose patients to the development of candidiasis. Proper education on rinsing the mouth or using a spacer device can minimize the development of candidiasis.[29,50,51]

Dental caries, erosion of enamel, periodontal disease, and oral candidiasis can be prevented with patient education. Discussing the importance of good oral hygiene, proper inhaler technique, and management of adverse effects of inhaled medications are key factors in prevention. See Table e15-8 on a summary of education points to be considered when discussing respiratory disorders and/or related medications with patients.[29,50,51]

TABLE e15-8

Patient Education Points for Respiratory Disorders

Medication-Related Education	Dental Specific Recommendations
1. Inhaler use ◦ Rinse mouth after any inhaler use with neutral or high pH mouth rinses ◦ Use a spacer ◦ Train patients on proper inhaler use 2. Manage xerostomia[a] ◦ Increase water consumption ◦ Sugar-free chewing gum ◦ Saliva substitutes	1. Stress the importance of good oral hygiene ◦ Regular dental appointments ◦ Antimicrobial mouthwash ◦ Fluoride toothpaste ◦ Avoid highly acidic/sweet beverages ◦ Toothbrushing: wait 30 minutes after rinsing mouth from inhaler use to allow enamel to reharden ◦ Use a soft-bristle toothbrush

[a] See xerostomia section in Chapter e16, "Oral Hygiene and Minor Oral Disorders."

Data from References 29,50,51.

PSYCHIATRIC CONDITIONS AND ORAL HEALTH

General Oral Health Concerns

⑨ Patients living with psychiatric conditions such as an eating disorder, anxiety, substance abuse, mood disorder, or conditions with severe symptoms (eg, bipolar disorder, schizophrenia) are at increased risk for poor oral health.[52,53] Those with psychiatric conditions are more likely to have comorbidities, such as diabetes and cardiovascular disease, which are associated with more severe oral disease outcomes than those without those disorders.[52] The prevalence of dental caries, oral lesions, tooth loss, and periodontal disease is significantly greater in those with psychiatric illness, a result of several factors, including poor oral hygiene, lack of motivation, dental anxiety, cost, and barriers to accessing dental care.[52,53] There has been more of a focus on oral health and mental health given the bidirectional evidence linking poor oral health to psychiatric disorders.[52]

⑩ Other contributory factors to poor oral health include comorbid substance use disorders involving alcohol and other substances, tobacco use, and poor dietary choices, particularly consumption of sugary foods and carbonated beverages.[52] The oral adverse effects of many psychiatric medications can also significantly contribute to declining oral health.[52,53] (Refer to Chapter e81 of this textbook for a complete review of psychiatric conditions.)

Tobacco Use and Oral Health

All forms of tobacco use can contribute to poor oral health and may worsen the oral health status of those with psychiatric disorders. Those who smoke are three times more likely to lose all their teeth than nonsmokers, and older adults (≥65 years and older) who smoke have a 33% greater risk of edentulism (loss of all natural teeth) compared with nonsmokers.[8] Smoking cigarettes is associated with periodontal disease, impaired healing, gingival recession, oral cancer, and oral lesions such as oral leukoplakia and nicotine stomatitis.[54] Of those aged 20 to 64 years old who smoke, about 40% had untreated tooth decay.[8] The use of smokeless tobacco has been linked to gingival keratosis, gingival recession, enamel erosion, alveolar bone damage, tooth loss, and periodontal disease. Dental caries can result from sugars added to the formulations. Cosmetic issues such as tooth discoloration and halitosis are also common.[54]

All healthcare providers, including pharmacists, should ask patients about their tobacco use and readiness to quit at each patient visit. Providing patient education on the risks of tobacco use along with options for nicotine replacement therapy are two simple methods for encouraging patients to quit. (Refer to Chapters e84, 85, and 86 for complete discussions of substance use disorders, including nicotine products.)

Substance Misuse and Oral Health

Substance misuse and substance use disorders are greatly associated with poor oral health outcomes because of direct links to the substance used as well as indirectly from the users' lifestyles and behaviors.[55,56] Poor oral hygiene, increased sugar consumption, and inability to receive dental care are contributing factors that result in negative oral health consequences.[55] Factors affecting oral health include direct exposure to drugs depending on the route administered, which can alter the normal physiology of the oral cavity and increase the risk of oral side effects such as xerostomia, dental caries, periodontal disease, and oral cancers.[56–58] See Table e15-9 for a summary of oral health adverse effects of substance-use disorders.[55,57,58]

TABLE e15-9

Oral Health Adverse Effects of Substance Use Disorders

Illicit Drug Type	Oral Adverse Effect(s)
Cannabis	Dental caries, gingival enlargement, increased risk of oral/neck cancer, leukoedema, periodontal disease, xerostomia
Opiates	Bruxism, burning mouth, candidiasis, dental caries, dysgeusia, impaired ability to eat, infections of mucosa, mucosal dysplasia, periodontal disease, xerostomia
Stimulants (eg, *Cocaine*, *Methamphetamine*)	Bruxism, changes in sense of smell[a], dental caries, dental erosion, difficulty chewing, gingival lesions/recession, nasal septum and sinus perforation[a], periodontitis, tooth sensitivity[b], xerostomia
Hallucinogens *(eg, LSD, Ecstasy)*	Bruxism, temporomandibular joint disorder, tissue necrosis, xerostomia

LSD, lysergic acid diethylamide

[a] Adverse effects from snorting method

[b] Adverse effect from topical application

Data from References 55,57,58.

Approach to dental care in patients who suffer from substance misuse or abuse disorder, should be provided comfort and de-stigmatization, to provide the best positive motivation to enhance their oral health as patients with substance misuse and abuse disorders often have general anxiety and dental fear.[55,56] (Refer to Chapters e84, 85, and 86 for complete discussions of substance-use disorders, including nicotine products.)

Psychiatric Medications and Oral Health Effects

There are several oral implications from medications used for psychiatric disorders and other nonspecific mental health conditions (eg, stress, sadness). Xerostomia and bruxism are further discussed in this chapter given that these oral side effects can result in worsening or progression of poor oral health if proper patient education or management is not provided.[29,53] See Table e15-10 pertaining to the oral side effects of the various psychiatric medication classes.[26–28,53] (Refer to Section 9 on Psychiatric Disorders of this textbook for more information on medications.)

TABLE e15-10

Oral Adverse Effects of Psychiatric Medication Classes

Psychiatric Medication Classes	Examples of Oral Adverse Effects[a]
Selective serotonin reuptake inhibitors	Bruxism, dysgeusia, dysphagia, gingivitis, sinusitis, stomatitis, tardive dyskinesia, xerostomia
Serotonin and norepinephrine reuptake inhibitors	Bruxism, dysgeusia, dysphagia, gingivitis, xerostomia
Atypical antidepressants	Angioedema, bruxism, dysgeusia, dysphagia, gingivitis, glossitis, stomatitis, xerostomia
Tricyclic antidepressants	Dysgeusia, hairy tongue, halitosis, salivary gland enlargement, stomatitis, tardive dyskinesia, tongue edema, xerostomia
Antianxiety agents	Dysgeusia, dysphagia, hypersalivation, SJS, xerostomia
First-generation antipsychotics	Dysphasia, bruxism, erythema multiforme, hypersalivation, tardive dyskinesia, stomatitis, xerostomia
Second-generation antipsychotics	Dysgeusia, dysphasia, hypersalivation, oral paresthesia, oral ulcers (ie, lichenoid reactions), sinusitis, tardive dyskinesia, tongue edema, xerostomia
Anticonvulsants	Dysgeusia, dysphagia, erythema multiforme, gingival enlargement, mouth/oral ulcers (ie, lichenoid reactions), sinusitis, SJS, TEN, xerostomia
Lithium	Dysgeusia, hypersalivation, lichenoid reactions, xerostomia

SJS, Stevens Johnson Syndrome; TEN, Toxic epidermal necrolysis

[a] Oral side effects may be specific to individual medications in that class and/or incidence of side effects may vary.

Data from References 26–28,53.

Xerostomia

Xerostomia, or dry mouth, is a very common but often overlooked adverse effect of many medications used to treat psychiatric conditions.[29,53,59] The anticholinergic effects of antidepressants, mood stabilizers, and psychotropic medications can decrease the production of saliva. The hyposecretion of saliva decreases the ability of the mouth to self-rinse, potentially leading to dental caries, erosion, tooth sensitivity, and periodontal disease.[59] There may be an additive effect in individuals taking multiple medications that cause salivary dysfunction, a common situation in patients with mental illness. In addition to medication adverse effects, lifestyle choices associated with patients with conditions such as alcohol consumption, tobacco use, and consumption of excessive cariogenic substances can also lead to xerostomia.[52,55]

Several strategies can be used to manage medication-induced xerostomia. Substituting a medication with a lower incidence of xerostomia—for example, switching from a tricyclic antidepressant to a selective serotonin inhibitor—can decrease the severity of dry mouth.[28,29] Saliva substitutes and saliva stimulators may also be recommended.[30,59] (See the xerostomia section in the Chapter e16, “Oral Hygiene and Minor Oral Disorders,” for more information.)

Bruxism

Bruxism, clenching or grinding of teeth, can be an adverse effect of antidepressants and antipsychotic medications that leads to jaw-muscle hypertrophy, fractured teeth, teeth pain/sensitivity, and temporomandibular disorders.[27,60] Bruxism is further classified as awake or sleep depending on whether the activity of bruxism occurs while one is asleep or awake.[60] The mechanism of action involves both serotonin and dopamine systems.[60] Serotonin suppresses the action of dopamine, which is responsible for preventing spontaneous movements. Lack of dopamine can induce spontaneous movements, resulting in bruxism. Cases involving bruxism in patients taking selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), and antipsychotics have been reported in the literature.[27,60] Bruxism was most reported with fluoxetine, sertraline, venlafaxine, and duloxetine. There are also several reports that psychostimulant medications such as methamphetamine, 3,4-methylenedioxymethamphetamine (MDMA), and piperazine can induce grinding of the teeth.[60]

Management for drug-induced bruxism should be reserved for those suffering from severe negative adverse impacts from bruxism such as attrition (ie, severe tooth wear) and high pain in masticatory muscles or temporomandibular joints.[60] Treatment considerations for bruxism caused by medications with serotonergic properties (ie, SSRIs or SNRIs) are lowering the medication dose, switching to an alternative agent, or adding buspirone, a dopamine agonist, to those who have poor response to their current medication.[60] Other medications that have been reviewed to potentially attenuate bruxism include botulinum toxin A, gabapentin, and hydroxyzine. For those without severe implications, suggested positive outcomes affiliated with bruxism include improving upper airway patency in those with obstructive sleep apnea.[60] Management of bruxism remains controversial because of mixed results reported in the literature. Additional large-scale studies need to be completed.[60]

Patient Education on Oral Health and Psychiatric Conditions

Educating patients with psychiatric conditions on oral health is a valuable opportunity for pharmacists and other healthcare professionals. Stressing the importance of good oral hygiene, such as regular brushing and flossing, along with providing education on oral health side effects are important first steps in this process.[30,52] Providers should also inquire about and assess specific medication-related oral side effects and assist in developing management options. (Refer to Tables e15-9 and e15-10 on oral-related adverse effects on mental health medications and substances). Pharmacists can also play an instrumental role in providing tobacco cessation education and counseling. Table e15-11 provides a summary of education points to be considered when pharmacists and other providers discuss psychiatric conditions and/or related medications with patients.[29,30,53,56–59]

TABLE e15-11

Patient Education Points for PsychiatricConditions

Medication-Related Education	Dental-Specific Recommendations
1. Manage xerostomia[a] ◦ Switch to an alternative agent with less anticholinergic effects ◦ Review other xerostomia-causing medications the patient may be taking ◦ Increase water consumption ◦ Sugar-free chewing gum ◦ Saliva substitutes 2. Manage bruxism ◦ Switch to alternative agent or decrease dose ◦ Add buspirone ◦ Mouth guard for nighttime 3. Tobacco cessation medication counseling[b] 4. Counseling about medications used for alcohol and substance use disorders[b]	1. Stress importance of good oral hygiene ◦ Regular dental appointments ◦ Antimicrobial mouthwash ◦ Fluoride toothpaste ◦ Avoid highly acidic/sweet beverages ◦ Use of electric toothbrushes and/or soft-bristled toothbrush 2. Tobacco cessation medication counseling[b] 3. Alcohol and substance abuse medication counseling[b]

[a] *See xerostomia section in Chapter e16, "Oral Hygiene and Minor Oral Disorders."*

[b] *Refer to Chapters e84, 85, and 86 for more details on tobacco, alcohol, and substance abuse.*

Data from References 29,30,53,56–59.

DISPARITIES IN ORAL HEALTHCARE

⑪ Oral health is important for people of all ages.[1,61,62] Barriers or disparities in oral care are important factors to identify when addressing how to ensure appropriate oral care from childhood to older age. Oral health disparities occur across the lifespan of several populations based on factors such as age, medical coverage, income, education, and race/ethnicity.

Oral Health Benefits

Lack of insurance coverage or other oral health benefits is a disparity that can affect access of patients to appropriate oral healthcare. Children without dental insurance are three times less likely to receive dental care and are three times more likely to have a concerning oral issue, when compared with children with dental insurance.[1,63] An estimated 51% of children are covered with private health insurance, 38.5% have dental benefits through Medicaid or the Children's Health Insurance Program (CHIP), and approximately 10% of those have no dental insurance coverage.[64] In the United States, publicly funded oral health insurance for children is provided through the Medicaid program or CHIP. Children enrolled are more likely to receive the necessary dental care; an increased in those receiving dental care has been noted from 37% in 2007 to 47% in 2011.[65]

Approximately 60% of employers offer dental benefits in the United States; these are less prevalent in blue-collar or service industries, compared with professional and technical occupations, and about one-third of adults have no dental benefits.[1,8,62,64] In the older adult populations in the United States, dental care services are often rendered as an out-of-pocket expense given the limited or lack of dental coverage in Medicare and/or loss of dental coverage when people retire.[1,6,62,64]

Unmet dental care in 80% of adults is due to the cost of care.[8] Overall, those who are uninsured are about three times less likely to seek out dental care needed due to cost.[66] Providing access to affordable dental care through private or public entities is essential to allow patients with no dental benefits to receive oral health care.[1,61,62]

Income and Education

Education status and income levels have been linked to disparities in oral health. Children living in low-income households have an increased incidence of untreated dental caries compared with those in higher income households.[10,67] In low income households, children ages 2 to 5 years old have an approximate threefold increase in untreated dental caries in their primary teeth, and those ages 12 to 19 years old are two times more likely to have untreated dental caries in their permanent teeth compared with those in the highest income household group.[10,61,67]

Adults with lower income and education also have a higher prevalence of dental caries, periodontal disease, tooth loss, and edentulism.[8,10,67] Adults aged 20 to 64 years old who have less than a high school education have a 30% higher incidence of untreated dental caries and are about four times more likely to have complete tooth loss compared to those with higher education.[10,67] Trends in untreated caries and edentulism are similar in this age group for low versus higher income households.[10] In the older adult populations, ages 65 years and older, the number with untreated caries and complete tooth loss, is nearly three times higher in both the lower income and educated group compared with higher income/education group.[10,67] Periodontal disease impacts about 47% of all adult Americans older than 30 years, and the rate increases to 70% in the older adult populations.[8] Overall, the incidence is more notable in those with lower education and lower income.[8]

The disparity of lower income and education on the progression of poor oral health is more pronounced as the group ages.[62,66] Overall, those with less than high school education and low income are almost two times more and 3 to 4 times more likely, respectively, to delay or not seek out dental care because of associated cost.[66] Early intervention is important in those with lower income/education to decrease the gap of oral health disparity seen later in life.

Race/Ethnicity

Compared to non-Hispanic White Americans, those of minority race and/or ethnicity have greater disparities in oral health.[1,10,61,67] The prevalence of dental caries is greater in children of Hispanic and non-Hispanic Black race/ethnicities compared with non-Hispanic White children, and the prevalence of dental caries changes as the child ages.[10] In primary teeth, the prevalence of dental caries increases for all groups by about 30%, and those of Hispanic race/ethnicity have the highest prevalence of dental caries (73%), followed by non-Hispanic Blacks (53%) and non-Hispanic Whites (44%). The prevalence of caries in permanent teeth in adolescents increases nearly 40% from those 6 to 11 years to those 12 to 19 years old, and the highest prevalence is found among those of Hispanic race/ethnicity (68%), followed by non-Hispanic Blacks (57%) and non-Hispanic Whites (54%).[10]

In the adult years, the prevalence of untreated tooth decay and periodontal disease increases in racial/ethnicity minorities.[10,61,67] Those of minority race/ethnicities were two times more likely to have untreated tooth decay, and three times more likely to have periodontal disease compared to non-Hispanic White adults.[61] The presence of edentulism was most prevalent in the non-Hispanic Black population ages 65 and older (approximately 30%) compared to Hispanics (16.7%) and non-Hispanic Whites (15.2%).[10] Minority race/ethnicities are more likely to experience poor oral health outcomes and when confounded with lower income are less likely to seek out dental care when needed.[66] Closing the gap on racial/ethnic disparity is imperative to improving the oral health from childhood to adult age.

INITIATIVES TO IMPROVING ORAL HEALTHCARE

Poor oral health can result in negative outcomes in both children and adults resulting in other serious conditions (eg, chronic pain, periodontitis), mastication issues, related nutrition problems, and social isolation.[1,2,10,61,62,67] Not only does poor oral health have physical concerns, this can impact a person socially due to embarrassment of discolored or missing teeth or inability to eat a normal diet; academic or work performance can also be affected.[1,61,62] For dental-related emergency department visits, about 30% were by Medicaid-enrolled adults and slightly more than 40% were by uninsured individuals.[64] As a result of unplanned dental visits for children, about 51 million hours annually are lost time at school, and those who have untreated tooth decay are four times more likely to have worse academic performance.[62,63] For adults, approximately 92.4 million hours are lost time at work because of unplanned dental visits, and more than $45 billion is lost in productivity.[67,68]

By the year 2050, people aged 60 years and older will account for about half of the growth of the world population.[69] The literature review of oral health and the connection to many noncommunicable diseases such as diabetes, cardiovascular diseases, respiratory conditions, and mental health, demands the need for increased awareness. Access to oral healthcare, and early intervention during childhood is important to lessen the disparities noted as the person ages.[1,2,62,70]

National Initiatives

⑫ The Surgeon General report on oral health states, “All Americans can benefit from the development of a National Oral Health Plan to improve quality of life and eliminate health disparities by facilitating collaborations among individuals, healthcare providers, communities, and policy makers at all levels of society.”[1] The US Department of Health and Human Services, continues a 10-year national objectives to improve oral health for all Americans, in part of the Healthy People 2030 initiative (see Table e15-12).[71] In this initiative, public health officials identified 15 objectives to address oral health in children, adolescents, and adults; access to preventive oral health services; interventions; monitoring systems; and public health infrastructure.

TABLE e15-12

Objectives and Target Goals for Healthy People 2030 Oral Health Initiative

Objectives	Baseline (%)	Target (%)
Oral Conditions—General		
Reduce the proportion of adults with untreated tooth decay (OH-3)	22.8	17.3
Increase the proportion of oral and pharyngeal cancers detected at the earliest stage (OH-7)	29.5	34.2
Increase use of the oral health care system (OH-8)	43.3	45
Adolescents		
Reduce the proportion of children and adolescents with lifetime tooth decay (OH-1)	48.4	42.9
Reduce the proportion of children and adolescents with active and untreated tooth decay (OH-2)	13.4	10.2
Health Care Access and Quality		
Increase the proportion of people with dental insurance (AHS-2)	54.4	59.8
Reduce the proportion of people who can't get the dental care they need when they need it (AHS-5)	4.6	4.1
Health Policy		
Increase the proportion of people whose water systems have the recommended amount of fluoride (OH-11)	72.8	77.1
Nutrition and Healthy Eating		
Reduce the consumption of added sugars by people aged 2 and over (NWS-10)	13.5	11.5
Older Adults		
Reduce the proportion of older adults with untreated root surface decay (OH-4)	29.1	20.1
Reduce the proportion of adults aged 45 years and over who have lost all their teeth (OH – 5)	7.9	5.4
Reduce the proportion of adults aged 45 and over with moderate or severe periodontitis (OH-6)	44.5	39.3
Preventative Care		
Increase the proportion of low-income youth who have a preventative dental visit (OH-9)	78.8	82.7
Increase the proportion of children and adolescents who have dental sealants on 1 or more molars (OH-10)	37	42.5
Public Health Infrastructure		
Increase the number of States and the District of Columbia that have an oral and craniofacial health surveillance system (OH-DO1)	To be established	

Data from Reference 71.

The Centers for Medicare & Medicaid Services (CMS) has recognized the imperative to improve access to oral health among children. Approximately 38% of dentists in the United States participate Medicaid or CHIP, and the geographical access to these providers within 15 minutes varies among the states.[64] In addition to the disparities described in the previous section, barriers to children receiving dental care include lack of transportation, language barriers, location of dental providers, and lack of parental understanding on the importance of oral health or the awareness of eligibility.[72] The CMS emphasizes the need for provider organizations at the state level to collaborate with dentists to increase provider rates as well as educate beneficiaries about the eligibility and importance of oral health.

For the older adult populations in the United States, dental services are not routinely covered under Medicare, but some Medicare Advantage programs provide oral health benefits.[73] Those adults who qualify for Medicaid also have a lack of coverage as it is an optional benefit the state is not required to provide; if provided, dental coverage is often limited.[64] Increasing access to oral healthcare is an objective of the Healthy People 2030 Oral Health initiative.[71] One method is through Federally Qualified Health Centers (FQHCs), which are nonprofit local organizations that provide services to low-income, underserved communities with a primary goal to enhance care regardless of insurance status or ability to pay. Additionally, the American Dental Association developed a program, Community Dental Health Coordinator (CDHC), to provide dental preventive services in underserved populations in rural, urban, and Native American communities.[74] Although programs are in place to help reduce the disparities and enhance access to oral care, additional factors need to be addressed such as health literacy, location of providers, transportation, and work/school flexibility for time off.[1,62,74]

Interprofessional Initiatives

⑬ Many organizations are leading coalitions to champion for increased access and awareness of oral health.[1,6,72,75,76] The Institute of Medicine along with other societies have proposed goals and principles for closing these gaps between professions to allow for enhanced interprofessional partnerships for improved oral health outcomes.[1,6,72,77] Including an oral exam in the general medical examination has been stressed; for instance, rather than the traditional Head, Ears, Eyes, Nose, and Throat (HEENT) examination, proponents have said this should include an oral exam (HEENOT).[1,6,38] Additional educational programming is needed for nondental health professionals, including oral health in the curriculum and workplace; a review shows that 70% of physicians have not received education on the role of specific oral health conditions (ie, periodontal disease) or related systemic effects.[6,37,77] The National Interprofessional Initiative on Oral Health aims to collaborate with the entire healthcare workforce and engage diverse organizations to enhance education in graduate healthcare schools and training on oral health in a variety of medical fields.[38]

Pharmacists can be champions for educating patients on general oral health and medication-related side effects.[78,79] In the community setting, a study showed about 70% of pharmacists address questions pertaining to patients' oral health, most frequently on mouth ulcers or dental pain.[79] Despite the importance of oral health and the frequency with which advice is provided, only about 30% of pharmacists stated they received oral health education in their academic training. Pharmacists in all settings can take a more active role in training and become better educated on oral health, its relationship with systemic health, and the impact of medications on oral diseases. Reviewing medication side effect profiles that involve the oral cavity as well as further exploring the connection between oral conditions and systemic conditions are ways pharmacists enhance their overall oral health knowledge (see Table e15-13).[29,80–87]

TABLE e15-13

Nondental Health Professional Patient Education Points for Additional Medical Conditions or Medication(s) and Impact on Oral Health or Dental Treatment

Medical Condition or Medications	Counseling Points
Newly initiated bisphosphonate or denosumab therapy[29,80]	*Inform the patient to:* - Seek dental care prior to initiating the medication - Maintain proper oral care and tobacco cessation

	• Call the prescribing provider to discuss a more optimal initiation date until after all necessary invasive dental treatment (eg, extractions, implants, bone grafting) is completed; above procedures may provoke osteonecrosis of the jaw *Inform dentist if any of the following symptoms occur:* • Pain, swelling, or infection of the gum or jaw • Bone exposure in the mouth • Jaw numbness or heaviness
Herbal and nutritional supplements[81,82]	*Inform patients:* • That many herbal and nutritional supplements can increase the risk of bleeding or other interactions with dental medications or procedures • To inform dental provider if taking any herbals or nutritional supplements • Inquire if any need to be stopped prior to a procedure
Anticoagulant or antiplatelet medications[83]	*Educate patient to:* • Inform both dental and medical provider of current medications • Inquire if/when anticoagulant/antiplatelet medication needs to be stopped prior to dental procedures
Immunocompromised patients[84]	*Instruct patient:* • To notify dental provider of condition • To update medical provider of upcoming dental procedures • Inform dentist if fever or illness is present • Inform dentist of any mouth ulcers, xerostomia, or difficulty swallowing
Oncology or head and neck cancer[85,86]	*Provide patient information to reduce risk of oral cancer:* • Avoid tobacco (any form) • Limit alcohol consumption • Use sunscreen on lips • Maintain good nutrition • Inform dentist if HPV positive • Receive HPV vaccine to help protect against some strains that can cause oropharyngeal cancers *Inform dentist if any of the following last longer than 2 weeks:* • Lesions inside the mouth or on the lips • Swelling, thickening, rough spot, or red or white patches • Pain, tenderness, or numbness in mouth or lips • Difficulty chewing, swallowing, speaking, or moving the jaw or tongue • An alteration in the way the teeth fit together when mouth is closed • Changes in the throat: soreness, feeling as if something is stuck, hoarseness, or numbness *If patient requires radiation or chemotherapy:* • Inform the patient to seek dental care prior to initiating treatment, if possible • Stress the importance of good oral hygiene during treatment • Inform patient to notify oncologist or dentist of any mouth ulcers or other mouth pain
Gastroesophageal reflux disease[87]	*Inform patient that:* • Acids from the stomach in addition to dry mouth, caused by medications to treat gastroesophageal reflux

	disease, can cause tooth erosion *Inform the dentist of any of the following:* • Increased tooth sensitivity with hot or cold beverages • Notice a yellowish discoloration of the teeth • Find that your fillings have changed *If patient suffers from gastroesophageal reflux disease, counsel patient to:* • See the dentist regularly • Chew sugar-free gum to increase saliva production • Use desensitizing toothpaste with fluoride to strengthen enamel • Avoid tobacco and alcohol

HPV, Human papillomavirus

The impact of pharmacists on oral health outcomes has not been widely documented or reviewed.[78,79] Some general resources for pharmacists and other nondental health professionals who want to enhance their knowledge of oral health include the American Dental Association, American Academy of Periodontology, Centers for Disease Control and Prevention, and Authority Dental.[8,75,76,88]

CONCLUSION

Oral health knowledge and education is important for all healthcare professionals to address their patients across their lifespan. The negative consequences of poor oral health can affect patients mentally, socially, and physically, which can decrease their quality of life and increase their risk of mortality and progression of other systemic conditions.[1–4,61] Disparities of oral health have been documented, and although oral health initiatives have been developed to increase emphasis on education and access to oral health, shortcomings are still noted.[1,38,61,62] Collaborative efforts from all healthcare professionals are ideal in promoting, educating, and screening oral health in patients. Until more profound measures are taken by health professionals, provider organizations, and policymakers, the responsibility of enhancing oral health is left to the individual practitioners taking care of patients, one person at a time.

ABBREVIATIONS

A1c	glycosylated hemoglobin
ACE	angiotensin-converting enzyme
AGEs	advanced glycosylation end products
ARB	angiotensin II receptor blockers
CCB	calcium channel blocker

SELF-ASSESSMENT QUESTIONS

1. Poor oral health is a modifiable risk factor for which of the following?

   A. Access to dental care

   B. Cardiovascular disease

   C. Cognitive improvement

   D. Tobacco use

2. Which option best describes the impact of untreated dental caries on children?

   A. Decreases academic success

   B. Enhances concentration

   C. Minimizes friendships

   D. Reduces nutritional status

3. Which of the following is a known risk factor for developing severe periodontitis?

   A. Body mass index greater than 30 kg/m^2

   B. Caucasian population

   C. Female gender

   D. Weakened immune system

4. Which of the following has been linked to a decrease in mortality?

   A. Denture use

   B. Mastication dysfunction

   C. Periodontal disease

   D. Tooth loss

5. Which of the following adverse reaction affects the orofacial soft tissue?

   A. Aphthae

   B. Bruxism

   C. Osteonecrosis

   D. Xerostomia

6. Which statement below **most accurately** describes the bidirectional relationship of periodontal disease and diabetes?

   A. Treatment of periodontal disease can lower A1c which can reduce complications of diabetes.

   B. Moderate-to-severe periodontitis increases the risk of neuropathy and cardiovascular events in patients with diabetes.

   C. Achieving optimal glycemic control will prevent periodontal disease.

   D. The presence of periodontitis is lower but more severe in those with diabetes.

7. Which oral health counseling point would be **most appropriate** to discuss with a patient receiving metformin and liraglutide for the first time?

   A. Advise the patient to hold his medications on the days of his dental visits to minimize the risk of hypoglycemia.

   B. Educate patient on the pemphigoid reactions with metformin and discuss his diabetes with his oral health provider.

   C. Inform the patient of the potential for metallic taste to occur with liraglutide, which should dissipate over time.

   D. Review how significant vomiting with these medications can result in dental erosion, and inform their provider if persistent vomiting occurs.

8. Which of the following options list the cardiovascular drug classes that are known to cause xerostomia?

   A. Alpha-adrenergic blockers, calcium channel blockers, and diuretics

   B. Alpha-adrenergic blockers, HMG-CoA reductase inhibitors, and peripheral vasodilators

   C. Anticoagulants, diuretics, and peripheral vasodilators

   D. Anticoagulants, calcium channel blockers, and HMG-CoA reductase inhibitors

9. Which option below lists the calcium channel blockers in order from lowest to highest incidence of gingival overgrowth?

   A. Amlodipine < nifedipine < verapamil

   B. Amlodipine < verapamil < diltiazem

   C. Diltiazem < nifedipine < verapamil

   D. Diltiazem < verapamil < amlodipine

10. Which of the following best explains a proposed mechanism on the formation of dental caries in patients using inhalers for respiratory disorders?

    A. The natural buffering effect in the oral cavity is disrupted, resulting in an acidic environment that enhances caries formation.

    B. Oral bacteria (ie, *S. mutans*) is decreased by changes in saliva production, which contributes to plaque development.

    C. An altered systemic immune response decreases the potential for gingival growth which increases the formation of dental caries.

    D. Immunosuppressive effects of lactose from inhaler use supports the growth of dental caries.

11. Which of the following contributes to poor oral health in those with mental health conditions?

    A. Medication-related adverse effects

    B. Occasional alcohol use

    C. Use of saliva substitutes

    D. Xylitol consumption

12. A patient presents to the pharmacy with a complaint of teeth grinding at night since initiating sertraline 4 months ago. What counseling point would be most appropriate now?

    A. Encourage the patient to increase water consumption and use saliva substitutes.

    B. Educate the patient to decrease the sertraline dose in half and monitor for changes in bruxism.

    C. Inform the patient you will call her provider to add buspirone to her medication regimen.

    D. Suggest the patient see a dental provider to obtain a mouth guard to use at nighttime.

13. Burning mouth, impaired taste and/or ability to eat, and mucosal dysplasia are oral adverse effects noted in which illicit drug class?

    A. Cannabis

    B. Opiates

   C. Stimulants (eg, *Cocaine*)

   D. Hallucinogens (eg, *Ecstasy*)

14. Which of the following lists disparities linked to an increased risk of dental caries?

   A. Easy access to dental insurance, higher education, and Hispanic race/ethnicity

   B. Lower income, older adult populations, and non-Hispanic Black race/ethnicity

   C. Lower education, older adult populations, and non-Hispanic White race/ethnicity

   D. Lack of access to dental insurance, lower education, and adolescent ages (12–19 years old)

15. Which medical condition or medication is accurately matched to its oral health side effect?

   A. Anticoagulants and infection

   B. Bisphosphonates and osteonecrosis

   C. Herbal supplements and dental caries

   D. Immunosuppressants and periodontitis

SELF-ASSESSMENT QUESTION-ANSWERS

1. **B.** Negative manifestations of oral health such as xerostomia and ulcerations may be a sign of a chronic disease such as diabetes and cardiovascular diseases. Access to dental care is a disparity linked to poor oral health outcomes. Cognitive decline is linked to poor oral health. Tobacco use results in poor oral health.

2. **A.** Untreated dental caries has been linked to reduced academic success. A child's ability to concentrate and quality of life are reduced in the presence of untreated caries. Nutritional status is seen mostly in adults as a result of tooth loss due to untreated dental caries. See "Dental Caries" section for more information.

3. **D.** Those with weakened immune systems have been linked to increased severity of periodontal disease. Hispanic and non-Hispanic Black populations and lower socio-economic status are also linked. Gender is not identified as a risk factor for severe periodontal disease.

4. **A.** Denture use was noted to be inversely related to mortality risk. Mastication dysfunction, periodontal disease, tooth loss, and dental caries are shown to increase mortality. See the Morbidity/Mortality Outcomes of Poor Oral Health section for more detailed review of the other oral health statuses.

5. **A.** Aphthae is an adverse effect that affects the soft tissue of the orofacial structure. Bruxism is non-specific, osteonecrosis impacts the hard tissues, and xerostomia is associated with the salivary structure.

6. **A.** Treatment of periodontal disease over 3 months is shown to reduce A1c and thereby reduce diabetic complications. Periodontal disease increases the risk of diabetic nephropathy, cardiovascular events, and mortality in those with diabetes. Achieving optimal glycemic goals may minimize progression or lessen the severity of periodontal disease. Refer to the "Diabetes and Periodontal Disease" section of the chapter for more information.

7. **D.** Liraglutide and metformin both are associated with vomiting as a side effect, which if persistent can result in dental erosion. Metallic taste is a side effect of metformin, and pemphigoid reactions occur with DPP-IV inhibitors. The administration of anti-diabetic medications on days of dental procedures should be discussed between the prescribing provider, oral health provider, and patient.

8. **A.** Alpha-adrenergic blockers, calcium channel blockers, and diuretics all cause xerostomia. HMG-CoA reductase inhibitors, peripheral vasodilators, and anticoagulants do not have a significant association with causing xerostomia. See Table e15-5 for more information.

9. **B.** Amlodipine as the lowest incidence of gingival overgrowth, followed by verapamil, then diltiazem or nifedipine with highest incidence noted.

10. **A.** Inhaler use may alter the pH of the oral cavity, thus modify its natural buffering effects, which increase the risk of the development of dental caries. Bacterial overgrowth may occur with inhaler use as a result of xerostomia. Although lactose in the formulation may be connected to dental caries, it is not an immunosuppressive. Immunosuppressive effects of inhaled corticosteroids is linked to increased risk of oral candidiasis. Periodontal disease is associated with an altered systemic immune response. See "Respiratory conditions and dental caries" section of the chapter.

11. **A.** Medication-related adverse effects is a contributory factor that may worsen oral health outcomes in patients with mental health disorders. Other factors include but aren't limited to poor oral hygiene, alcohol misuse, lack of motivation, dental anxiety, cost, barriers to care, poor diet (ie, high in sugars/carbonated beverages), tobacco and illicit substance misuse. Xylitol is an anti-cavity fighting agent. Saliva substitutes are appropriate to treat xerostomia.

12. **D.** Since the patient was newly initiated, it would be most optimal now for the patient to obtain a mouth guard that is appropriately fitted. Adding buspirone would be appropriate when a patient is already maximally treated for the mental health condition, no other alternative is available, and the bruxism is severe. Dose adjustments should be made by the prescribing provider. Water consumption and saliva substitutes are for patients with xerostomia. See Table e15-11 for more information.

13. **B.** Opiates are associated with impaired taste and/or ability to eat, mucosal dysplasia, and burning mouth. See Table 15-9 for oral health adverse effects of illicit drug use.

14. **B.** Disparities linked to increased dental caries are lack of access to dental care/insurance, lower education and income, and those of minority race/ethnicities.

15. **B.** Bisphosphonate may cause medication-induced osteonecrosis of the jaw. For clarification on other conditions and oral health counseling point see Table e15-13.

Chapter e16: Oral Hygiene and Minor Oral Disorders

Anna Milone; Kristyn Williamson; Maren Hall

KEY CONCEPTS

KEY CONCEPTS

① Dental caries is one of the most common chronic health conditions in both children and adults. Dental caries stems from an imbalance in saliva defense, microbial load, and lifestyle habits. Modifiable risk factors include oral hygiene practices and lifestyle factors. Dental caries can lead to tooth sensitivity, cause oral pain, and have implications for overall health.

② For oral health maintenance, teeth should be brushed twice daily with fluoride toothpaste. Patients should floss daily and follow recommended technique for brushing and flossing. Oral health maintenance also includes the use of athletic mouthguards, denture care, and regular dental care by an oral healthcare professional.

③ Toothpaste contains fluoride as its primary active ingredient to prevent tooth decay and gum disease. Other active ingredients, such as potassium salts, may be added for tooth sensitivity, as well as abrasives and carbamide peroxide for tooth whitening.

④ The first-line treatment for dental pain is nonsteroidal anti-inflammatory drugs (NSAIDs), with or without acetaminophen.

⑤ Benzocaine is available over-the-counter (OTC) in numerous products for adults, children, and infants as a local anesthetic for oral pain. While widely available, benzocaine has significant safety concerns and should not be used for teething pain in children younger than 2 years of age.

⑥ Canker sores are one of the most common ulcerative conditions of the mouth. Treatment options include pain management with topical agents and eliminating irritating food and drink from the diet.

⑦ Cold sores are recurrent oral lesions resulting from infection with herpes simplex virus type 1. Referral of patients to their primary care physician is likely warranted, as the most effective treatment options are available as prescription only products.

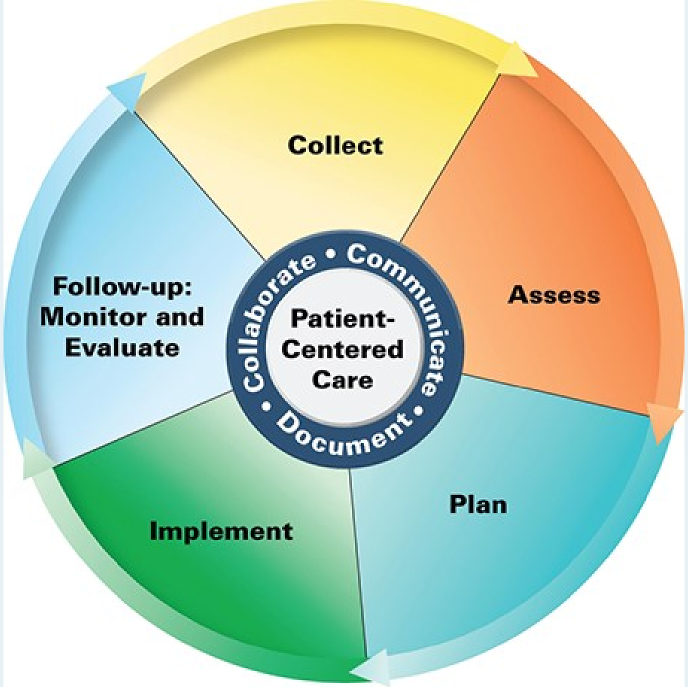
⑧ Xerostomia or dry mouth is a common oral condition often caused by medical conditions, medications, or medical treatments. Treatment of xerostomia greatly depends on the cause of the condition, but can be treated symptomatically with a number of OTC products.

⑨ Dentistry has few true emergencies; however, dental trauma where a permanent tooth is displaced or avulsed constitute a dental emergency, and immediate referral to an oral healthcare provider or urgent care center is warranted.

⑩ Fluoride is effective in preventing dental caries by inhibiting the demineralization of tooth enamel, enhancing the remineralization of enamel, and inhibiting bacterial enzymes involved in the metabolism of carbohydrates by cariogenic bacteria. Sources of fluoride include toothpaste, fluoridated drinking water, professionally applied topical fluorides, and oral fluoride supplementation.

PATIENT CARE PROCESS

Patient Care Process for Xerostomia



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Collaborate • Communicate • Document •
Patient-Centered Care

Collect

- Patient characteristics
- Patient medical history (personal and family)
- Social history and dietary habits (eg, smoking status, daily water consumption)
- Current medications

Assess

- Hydration status
- Presence of precipitating factors (see Table e16-12)
- Emotional status (eg, presence of anxiety and/or depression)
- Impact on quality of life (eg, difficulty speaking, swallowing, chewing)
- Severity of condition (eg, affecting surrounding tissues, presence of complications)
- Willingness to quit smoking (if applicable)
- Ability/willingness to try nonpharmacologic treatment options
- Ability/willingness to pay for pharmacologic treatment options

Plan*

- Patient education (eg, dietary and lifestyle modifications, information on precipitating factor(s), frequency of use of pharmacologic treatments)
- Self-monitoring for resolution of symptoms

- Referrals to other providers when appropriate (eg, dental professional, prescriber of precipitating medication, primary care physician)

Implement[*]

- Provide patient education regarding all elements of treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence
- Schedule follow-up

Follow-up: Monitor and Evaluate

- Resolution of symptoms (eg, dryness, redness, peeling, cracking, or oral tissues)
- Presence of treatment specific adverse effects
- Patient adherence to treatment plan

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Explore the oral health section of either the Centers for Disease Control and Prevention (CDC) website: https://www.cdc.gov/OralHealth/index.html), or the oral health portion of http://healthychildren.org by the American Academy of Pediatrics (AAP): https://www.healthychildren.org/English/healthy-living/oral-health/Pages/default.aspx). You can explore overview topics, Question and Answer sections, or topics that stimulate your interest. Find at least one topic that relates directly to community pharmacy practice or the primary care setting, such as the use of OTCs or educating patients. What areas of oral health do you feel knowledgeable in, and in what areas do you have gaps in knowledge? You may wish to reflect on any patient questions you have received on oral health topics. You may also wish to explore (either online or in person) the oral health section of a pharmacy. How large are these sections, and what products are available?

INTRODUCTION

Dentists and other members of the dental community are actively encouraging the involvement of additional health professionals in identification, referral, and in some cases treatment of patients with oral health conditions. Pharmacists, particularly community and health-system pharmacists, are the most accessible health professionals for patients presenting with oral health issues or questions. Furthermore, community pharmacies carry many products for oral health ranging from toothbrushes and mouthguards to rinses and pain relievers. Patients with oral pain, poorly fitting dentures, or a need for an athletic mouth guard often first enter a pharmacy seeking a solution, making the pharmacist the first healthcare professional they meet. It is important for the pharmacist and other primary care providers to have an understanding of the dental products available and be able to provide referrals and recommendations regarding oral health. Pharmacists and other primary care providers are integral parts of the collaborative interprofessional healthcare team, and dentists, dental hygienists, dental assistants, and dental therapists are also important and sometimes unrecognized members of this team.

To enable pharmacists and other primary care providers to improve their skills and knowledge relative to oral health, this chapter begins with a review of relevant tooth anatomy and pathophysiology, providing an important foundation for understanding oral health conditions. From there, the discussion moves to oral health maintenance, specific oral health conditions, and concludes with a focus on pediatrics. Oral health prevention and maintenance are vital for both public health and individual well-being. All members of the healthcare team have an important responsibility to recognize that oral health is an important part of the overall health of each individual.

EPIDEMIOLOGY

Untreated dental disease in children can lead to complications with eating, learning, and speaking. More than 90% of adults aged 20 to 64 years of age have at least one cavity, leading to pain, loss in productivity, and increased healthcare costs. Up to 26% of adults in the United States have untreated tooth decay, and large disparities exist in oral health and access to dental treatment. Periodontal disease, often called gum disease, also affects a large portion of the population. An estimated 46% of adults aged 30 and older in the United States show signs of gum disease. Furthermore, oral health is linked to many other chronic diseases, including heart disease and diabetes, making good oral health vital for overall health.[1]

Oral cavity and pharynx cancer is estimated to occur in 54,010 people in the United States in 2021, with a lifetime risk of 1.2% of men and women diagnosed at some point during their lifetime. Men are twice as likely as women to be diagnosed with oral cavity cancer, and oral cancers are more commonly diagnosed in people over 55 years of age.[2]

Additionally, oral health issues are common in older adults, and unfortunately many older adults do not have dental insurance. By age 65, 96% of adults have at least one cavity and 68% have periodontal disease. An estimated 26% of adults 75 and older have complete tooth loss, which has significant effects on nutrition, health, and healthcare utilization. The greater incidence of polypharmacy in older adults increases the risk of dry mouth as a therapeutic side effect, which can further worsen oral health.[3]

Healthy People 2030 includes multiple objectives relating directly to oral health, including the reduction of oral health inequities and increasing access to oral health care. Indeed, use of the oral health care system by all age groups is a leading health indicator. Many of the oral health objectives focus on reducing tooth decay in the population.[4] Oral health is also an area of significant public health investment, including community water fluoridation and other oral health programs. Because pharmacists are so easily accessible, their role in promoting oral health for individual patients can positively impact public health as well.

TOOTH ANATOMY

Understanding tooth anatomy is important in order to better comprehend the mechanisms of dental disease and the treatment of oral conditions. There are four tissues of a tooth, three hard tissues—enamel, cementum, and dentin—and one soft tissue, pulp. Each tooth has a crown, covered with enamel, and a root, hidden under the gums in the bone and covered with cementum. Enamel is the most highly mineralized and hardest substance in the body. The primary mineral of enamel is hydroxyapatite, which is a crystalline calcium phosphate. Cementum is a dynamic entity with both acellular and cellular parts, surrounding the root of the tooth. Internal to the enamel and cementum, in both the crown and the root of the tooth, is dentin. Dentin makes up the bulk of the tooth structure, consisting of tubules surrounded by highly mineralized peritubular dentin and a softer intertubular matrix.[5] Encased by the hard outer layers of enamel, dentin, and cementum, the pulp occupies the most internal space of a tooth. The pulp consists of connective tissue, nerves, and blood vessels.[6]

A healthy tooth is held in place within the alveolar bone by the periodontal ligament (PDL). The PDL attaches the cementum on the root of the tooth to the alveolar bone in the tooth socket. The gums, or gingiva, cover the bone and in a healthy state are tight against the tooth. A small fold is present between the gum and the tooth, creating the gingival sulcus, or pocket, which is usually shallow when the gingiva is healthy.[6]

PATHOPHYSIOLOGY

Dental Caries

① Dental caries is the complex bacterial biofilm disease of the oral cavity involving net demineralization of the dental tissues resulting from prolonged periods of low pH. Caries result from acid production by acidogenic bacteria that thrive in the plaque biofilm. The traditional concept of dental caries is an imbalance in salivary defense, microbial load, and lifestyle habits like sugar consumption. The ecological plaque hypothesis is generally accepted, where “cariogenic bacteria,” are understood to be normally present on all teeth, and an environmental change in the biofilm favors the growth of these specific pathogens, notably *Streptococcus mutans* and *Lactobacillus*.[8] Symptoms of dental caries are listed in Table e16-1.

TABLE e16-1

Symptoms of Dental Caries

- Tooth sensitivity
- Mild-to-sharp pain when eating or drinking something sweet, hot, or cold
- Visible holes or pits in teeth
- Brown, black, orange, or white staining on tooth surfaces
- Pain on biting
- Toothache, spontaneous pain

Data from Reference 7.

Caries risks are not static over a lifetime. Host genotypes, microbiomes, lifestyle, and oral hygiene contribute as independent influential factors to the complex etiology.[8]

Periodontal Disease

Periodontal disease is the leading cause of tooth loss. It typically begins with gingivitis, which is inflammation of the gingiva that does not result in attachment loss or loss of bone. The gums become red, swollen, and bleed easily.

Gingivitis is reversible with professional treatment and good oral hygiene. Untreated gingivitis can advance to periodontitis, the destruction of the tissues and bone that support the teeth. Bacterial plaque hardens the teeth, forming calculus. An inflammatory host response against the microorganisms of the bacterial plaque and their toxins occurs. The intense inflammatory reaction results in gums separating from the teeth and the creation of pockets that become infected. Genetic and systemic factors may affect these events. *Porphyromonas gingivalis* and *Aggregatibacter actinomycetemcomitans* bacteria have been indicated in the pathogenesis of adult periodontitis. As the pockets deepen, more gum tissue and bone is destroyed. Often only mild symptoms are present throughout progression of the disease, until the teeth become loose, and sometimes have to be removed. Periodontal disease can result in tender, red, swollen, loose, or bleeding gums, painful chewing, loose and/or sensitive teeth, as well as changes in the way teeth fit together when biting or the fit of partial dentures.[9]

Poor oral hygiene is a risk factor for development of periodontal disease. Other important risk factors include smoking, poorly controlled diabetes mellitus, stress, underlying immunodeficiencies, and dry mouth. Age, socioeconomic status, education, race, and genetics also correlate with prevalence of periodontal disease.[10]

Treatment of periodontal disease requires the intervention of an oral healthcare professional. Calculus must be removed in order to decrease the bacterial load and inflammatory response. Discussions about managing other contributing factors and developing a treatment and maintenance plan are important components of stabilizing the disease and decreasing risk of its progression.

ORAL HEALTH PREVENTION AND MAINTENANCE

② Oral health prevention and maintenance includes both daily habits that comprise oral hygiene practices, as well as routine care by oral healthcare professionals. Most of the products recommended for daily oral health maintenance are available over-the-counter (OTC), making pharmacists and other nondental health professionals valuable resources in providing oral healthcare and patient education.

Daily Habits

Toothbrushing

It is widely recommended that patients brush their teeth with a fluoride toothpaste for a duration of 2 minutes twice daily. Brushing for a period of 2 minutes achieves clinically significant plaque removal, removing more plaque than when teeth are brushed for only 1 minute. Patients should also be counseled to divide each brushing session into 30 second segments for each quadrant of the mouth.[11] Some toothbrushes have incorporated timers into the toothbrush design for this purpose. Although studies are lacking to evaluate the efficacy of built-in timers, these may be useful for patients who have difficulty brushing for the recommended amount of time.[12]

Toothbrushing technique is also important for plaque removal. Multiple toothbrushing techniques have been published, but studies have not reliably demonstrated one method to be superior for all patients. In general, the toothbrush should be placed at the gumline at a 45° angle to remove plaque optimally at the gingival margin. Patients should apply gentle force to insert the toothbrush into the sulcus. The toothbrush should be moved in a vibrating motion in short strokes while remaining in contact with the sulcus. All surfaces of the teeth (inner, outer, and chewing surfaces) should be brushed during each session.[13]

The choice of toothbrush bristles is important as well. Soft bristles minimize the risk of gingival abrasion or injury during brushing. While medium bristles are effective at plaque and biofilm removal, they carry a risk of gingival damage. This risk can also be minimized by educating patients to apply gentle pressure when brushing and to avoid overly forceful brushing. Multilevel or angled bristles remove plaque more effectively than conventional flat-trimmed brushes. Toothbrushes should be replaced every 3 to 4 months, replacing more frequently if bristles are visibly frayed or matted.[13]

Electric-powered toothbrushes are available in a variety of designs. Patients can be assured that electric toothbrushes are at least as effective as manual toothbrushes. Studies of electric toothbrushes have shown statistically significant improvement in dental plaque removal when compared with a manual toothbrush, but the difference may not be clinically meaningful. In general, electric toothbrushes are likely more expensive, but some patients may find them easier to use. It seems there may be meaningful benefit for using electric toothbrushes for those patients who may have difficulty with brushing technique. This may include patients with special needs, patients requiring a caregiver for activities of daily living, patients with manual dexterity deficits, as well as older adults, children, and those with braces. Electric toothbrushes are available with various types of head movements, including side-to-side, rotating oscillating, circular, and ultrasonic. A Cochrane review found that rotating oscillating and ultrasonic designs were more effective in reducing plaque than conventional manual toothbrushes. However, other studies have found conflicting results; choice of electronic toothbrush design remains largely based on patient preference.[13]

Toothbrushes can also earn the American Dental Association (ADA) Seal of Acceptance, indicating the toothbrush is safe and effective for the removal of plaque and reduction of gingivitis. The ADA Council on Scientific Affairs reviews data on defined parameters and grants the seal to those products meeting its requirements. While considering bristle softness, toothbrush shape, and manual or electric toothbrushes, patients can also examine whether or not the product has the ADA Seal of Acceptance. Overall, patients should be encouraged to choose the toothbrush they prefer and will be able to use most consistently in order to promote adequate brushing practices.[13]

Toothpaste

Fluoride is anticariogenic, meaning it prevents tooth decay. Significant clinical studies support the use of fluoride in dental care, recommending that patients brush teeth twice daily with a fluoride toothpaste. Fluoride strengthens tooth enamel by both inhibiting the demineralization of enamel, as well as enhancing the remineralization of decalcified enamel in the early stages of tooth decay. When given systemically prior to the eruption of permanent teeth, the fluoride ion is incorporated into the apatite crystal of the bone and teeth, stabilizing and strengthening the tooth.[14] Topical fluoride is also incorporated into the enamel structure, thus fluoride is still effective for caries prevention in children and adults with permanent teeth.[15] Fluoride incorporated into the enamel increases the enamel’s resistance to acid, inhibiting the demineralization of enamel. Enamel with a greater concentration of fluoride has an improved structure and is more resistant to acid.[16] In decalcified enamel, fluoride present in the oral cavity can be incorporated into enamel structure and promotes remineralization of enamel, protecting the tooth from decay.[15] Additionally, fluoride inhibits the metabolism of carbohydrates by cariogenic bacteria, preventing the creation of an acidic byproduct that leads to demineralization of tooth enamel.[16]

Patients may encounter fluoride from multiple sources, including toothpaste, mouthwashes, and fluoridated water. Fluoride exerts a topical effect when in direct contact with teeth, such as when drinking fluoridated water, brushing with a fluoride toothpaste, or using a fluoride mouthwash. Additionally, any ingested fluoride increases the fluoride concentration in the saliva, extending the protective effects.[16]

Fluoride is available in toothpastes as sodium monofluorophosphate, sodium fluoride, and stannous fluoride. Prescription strength toothpastes have a greater concentration than OTC toothpastes and result in a greater prevention of caries. However, studies with OTC toothpastes have still found them to be effective in caries prevention and control. Toothpastes may contain additional active and inactive ingredients. These are summarized in

Table e16-2.[16]

TABLE e16-2

Toothpaste Ingredients and Their Functions

Category	Ingredients	Indication/Purpose
Fluoride	Sodium monofluorophosphate, sodium fluoride, and stannous fluoride	Prevention of dental caries
Antimicrobial	stannous fluoride	Reduce gingivitis
Anti-hypersensitivity	Potassium salts, stannous fluoride, calcium sodium phosphosilicate	Reduce tooth sensitivity
Abrasive agents	Modified silica abrasives or enzymes (calcium carbonate, dehydrated silica gels, hydrated aluminum oxides, magnesium carbonate, phosphate salts, silicates)	Whiten teeth by physically removing surface stains
Detergents	Sodium lauryl sulfate, sodium *N*-Lauryl sarcosinate	Foaming action. May help increase the solubility of plaque during brushing
Flavoring agents	Noncaloric sweeteners (sugar is cariogenic and is not permitted in ADA-accepted toothpaste)	Flavor
Humectants	Glycerol, propylene glycol, sorbitol	Prevents water loss in the toothpaste
Thickeners	Mineral colloids, natural gums, seaweed colloids, synthetic cellulose	Binding agents to stabilize toothpaste
Peroxides	Hydrogen peroxide, carbamide peroxide	Reduce extrinsic stains
Other	Essential oils, fragrance, menthol, zinc or potassium citrate	Flavor and fragrance

Data from Reference 16.

③ Toothpaste ingredients may cause contact dermatitis. Common allergenic ingredients in toothpastes include essential oils, such as spearmint, peppermint, or cinnamon. It is important to note that specific essential oils may not be listed in the ingredients and instead may be mentioned as flavors. Other potential irritants include citric acid in the form of zinc or potassium citrate, menthol, fragrances, sodium lauryl sulfate (SLS), propylene glycol, parabens, pyrophosphates, PEG-8, PEG-12, PEG1450, and cocamidopropyl betaine. As with toothbrushes, toothpastes may also carry the ADA Seal of Acceptance. Toothpastes must meet requirements created by the ADA Council on Scientific Affairs related to fluoride availability and absorption. Note that a variety of toothpastes marketed as having natural ingredients may not contain fluoride, and thus will not have proven anticariogenic activity nor have an ADA Seal of Acceptance.[16]

Recommendations for toothbrushing and toothpaste for children are discussed in section "Pediatrics" of this chapter.

Flossing

Flossing or interdental cleaning is recommended once daily in order to reduce the likelihood of gum disease and tooth decay. While patients may struggle to floss regularly, it is an essential part of daily oral health maintenance. The purpose of flossing is to remove debris and interproximal dental plaque, or plaque that collects between teeth. Plaque not removed from the teeth may harden into calculus, potentially leading to gingivitis.[17]

Dental floss is made of nylon or plastic filaments. Floss may have flavoring agents and is available both waxed and unwaxed. The best time of day to floss is whenever it will be performed most regularly. Flossing can occur before or after toothbrushing, or at a different time altogether.[17] Flossing is a technique-sensitive intervention, and patients should discuss proper flossing technique with their oral healthcare professional.[18] Proper flossing technique is included in Table e16-3.[19] Other interdental cleaners available include prethreaded flossers, dental picks, wooden plaque removers, interproximal brushes, and water flossers.[17] Not all interdental cleaners are appropriate for all patients, and patients should consult their oral health professionals for individualized recommendations.[18]

TABLE e16-3

Proper Flossing Technique

- Wind 18 in. (45 cm) of floss around the middle fingers of each hand
- Pinch 1-2 in. (2.5-5 cm) of floss behind thumb and index finger, keep taut between fingers
- Gently guide floss between the teeth, guiding with the thumb and index fingers
- Gently wrap floss around the side of the tooth
- Slide floss up and down against the tooth surface and under the gumline

Data from Reference 19.

Mouthwashes

Mouthwash may be used daily, offering further benefits in addition to brushing and flossing. Specifically, mouthwash may reduce bad breath, as well as reduce plaque and gingivitis. It is important to educate patients that mouthwash cannot replace brushing and flossing, but instead should be used in addition. Mouthwashes may also have the ADA Seal of Acceptance. Table e16-4 lists active ingredients that may be found in mouthwash.[20]

TABLE e16-4

Active Ingredients in OTC Mouthwash

Active Ingredients	Indication/Purpose	Clinical Pearls
Cetylpyridinium chloride	Reduce bad breath, plaque, and gingivitis	Antimicrobial action
		May cause brown staining of teeth, tongue, and/or restorations
Essential oils such as eucalyptol, menthol, thymol, methyl salicylate	Reduce bad breath, plaque, and gingivitis	May be a potential allergen or irritant for some patients
Fluoride	Prevent tooth decay	Effective topically to prevent dental caries
Peroxide	Tooth whitening	Present in whitening mouthwashes

Data from Reference 20.

Oral malodor, also called halitosis or bad breath, can result from volatile sulfur compounds arising from breakdown of foods and plaque or bacteria associated with oral disease. Antimicrobial-containing mouthwashes may be effective for more long-term control of oral malodor. The use of mouthwashes containing antimicrobials are associated with a decreased risk of gingivitis and periodontal disease. Cosmetic mouthwashes are those that contain no antimicrobials or fluoride, and these provide only a temporary benefit for bad breath. Mouthwashes may also contain alcohol. Alcohol consumption is a risk factor for oral cancers, although studies have not demonstrated an association between mouthwash use and oral cancer. Since alcohol may also worsen xerostomia, alcohol-containing mouthwashes should be avoided in patients experiencing xerostomia. Mouthwashes should not be used in children under 6 years of age because of the concern that they may swallow a large quantity.[20]

Chlorhexidine mouthwash is available only by prescription and is indicated for treatment of gingivitis and periodontitis.[21] Chlorhexidine rinse may also prevent alveolar osteitis (dry sockets) after a tooth extraction. Potential adverse reactions include staining of teeth, dentures, and tongue, as well as altered taste.[20]

Dental Visits

The ADA recommends all patients regularly visit a dentist or oral healthcare professional for the prevention and treatment of oral disease. The frequency of dental visits should be determined by an individualized case management protocol based on the patient’s caries risk level, age, and compliance or engagement with oral health preventive strategies. Frequency of visits range from every 12 months for a patient with low risk of oral disease to every 3 months for patients at high risk. Visits include regular cleanings, assessments for oral conditions, such as dental caries, periodontitis, and oral cancer, and guidance on oral health maintenance. Patients should expect their oral healthcare professional to design an oral health maintenance regimen that is tailored to the patient, provide education on lifestyle changes related to oral health, and provide guidance on the use of oral healthcare products.[11] The chronic condition of oral disease dictates that oral health recommendations should focus on prevention and maintenance protocols.[4]

Denture Care

Edentulism, defined as the loss of all permanent teeth, affects an estimated 26% of the US population over 75 years of age.[22] Many of these individuals wear complete dentures as a prosthetic to enhance esthetics and function. Dentures accumulate plaque, stain, and calculus similar to the natural dentition. In 2009, the American College of Prosthodontists developed evidence-based guidelines for the care and maintenance of complete dentures (see Table e16-5).[23]

TABLE e16-5

Guidelines for Care and Maintenance of Complete Dentures

1. Careful daily removal of the bacterial biofilm present in the oral cavity and on complete dentures is important to minimize oral tissue irritation (denture stomatitis).
2. Dentures should be cleaned daily by soaking and brushing with an effective, nonabrasive denture cleanser. Afterward, they should be thoroughly rinsed before putting them back inside the mouth.
3. Commercially available denture cleansers use various active agents, including hypochlorites, peroxides, enzymes, acids, and oral mouth rinses to remove biofilm from dentures. Denture cleansers are not to be used inside the mouth.
4. Dentures should never be placed in boiling water.
5. Dentures should not be soaked in bleach, or products containing bleach, for periods of more than 10 minutes.
6. Dentures should be stored immersed in water when not in use.
7. Dentures should not be worn continuously (24 hours per day) as this can cause denture stomatitis.
8. Patients who wear dentures should see a dentist annually for maintenance of the denture and evaluation of the health of the oral cavity and associated tissues.

Data from Reference 23.

Use of Denture Adhesives

Denture adhesives can improve the retention and stability of dentures, helping prevent the accumulation of food particles beneath the dentures.

However, evidence regarding the effects of denture adhesives on the oral tissues when used for periods longer than 6 months is lacking. Thus, extended use of denture adhesives should only be undertaken with periodic assessment by a dental professional.[23]

Denture adhesives are available in multiple forms, including paste, cream, powder, and pads. The necessary quantity of denture adhesive should be minimal and should be completely removed from the prosthesis and the oral cavity on a daily basis. Manufacturers instructions for use should be followed. If increasing amounts of adhesive are necessary for the patient to feel comfortable, a dental professional should be consulted in order to evaluate the prosthesis and oral tissues.[23]

Temporomandibular Disorders

Temporomandibular disorders (TMDs) encompass a wide group of clinical problems involving the masticatory musculature, the temporomandibular joint, and the surrounding bone and soft tissue. TMD is a multifactorial disease process with various causes including parafunctional habits (bruxing, clenching, lip or cheek biting), instability or laxity of the temporomandibular joint, trauma to the jaw, and comorbidity with other rheumatic or musculoskeletal disorders. The prevalence of TMD is thought to be 6% to 12% of the population, with about 5% having signs and symptoms warranting treatment. TMD symptoms are more prevalent in women than men, with peak occurrence between 20 and 40 years of age. See Table e16-6 for common symptoms of TMD.[24]

TABLE e16-6

Symptoms of Temporomandibular Disorder

- Muscle and joint pain, acute or chronic
- Radiating pain to the ears, neck, and head
- Joint noise (clicking, popping, crepitus)
- Functional limitations such as decreased range of motion and jaw locking

Data from Reference 24.

Diagnosis of TMD requires a focused history and physical examination. The use of radiographs and magnetic resonance imaging may aid in determining degenerative changes. Images combined with clinical presentation, signs, and symptoms will allow the clinician to develop a diagnosis and treatment plan. Treatment should initially center on conservative, reversible, and evidence-based modalities. Only after failure of noninvasive options should invasive and nonreversible treatments be performed.[24]

Bite Guards

A variety of bite guards, also known as occlusal splints, oral orthotics, and oral appliances, are available with differing designs and functions. Patients often seek them out to alleviate symptoms of TMD and bruxism. Bite guards can be custom made or bought OTC. They seem to be an effective treatment for many temporomandibular disorders and nocturnal use may improve sleep quality. Evidence also supports oral appliance treatment for sleep bruxism and protection of teeth, but it is insufficient to support its role in the long-term reduction of sleep bruxism activity. Therapeutic mechanisms of occlusal splints are not yet clarified; suggestions have been made that occlusal splints can reestablish symmetric activity in the temporal and masseter muscles. An occlusal splint may contribute to reducing myofascial pain, improving quality of life, and protection of teeth, although it does not cure temporomandibular dysfunction.[25]

There is little evidence to prove the theory behind any one bite guard design[26]; however, full coverage splints (covering the biting surfaces of all teeth of one arch) are often recommended to evenly distribute forces from the masticatory muscles to the teeth and to prevent unwanted changes in tooth or bite position.[27] With the availability of OTC splints in the community pharmacy, patients may bypass their dentist, which can have many significant risks. Not least, it relies on the consumer to diagnose their condition without the help of a dental professional, which may be inaccurate and delay appropriate treatment. Additionally, there is little consistency across safety warnings or stated indications for use of OTC splints, which can result in confusion or improper treatment of a condition.

The use of poorly fitting appliances can have unintended consequences. Changes in the dentition, tooth movement, gingival trauma, and increased TMD symptoms are all possible risks of using occlusal splints.[28] In general, patients should use caution in self-selecting OTC occlusal splints and consultation with an oral healthcare professional is recommended prior to purchasing an oral appliance for daily use.

Athletic Mouthguards

A mouthguard, also known as a mouth protector or sports guard, is an appliance that covers the teeth and surrounding mucosa with the aim of preventing or reducing trauma to the teeth, gingival tissue, lips, and jaws. Mouthguards may also play a role in preventing and reducing concussion by absorbing impact forces, although the evidence for this is less conclusive. Nearly one-third of all dental injuries are sports related. Dental traumatic injuries can carry a hefty financial and physical burden over an individual's lifetime. Numerous surveys of sports-related dental injuries have documented that participants of all ages, genders, and skill levels are at risk of sustaining dental injuries in sporting activities, including organized and unorganized sports at both recreational and competitive levels. While collision and contact sports, such as boxing and football, have inherent injury risks, dental injuries are also prevalent in noncontact activities and exercises, such as gymnastics, bicycling, baseball, and skating. Mouthguards can be effective in reducing the incidence of dental injury in sport.[29]

Mouthguards are typically composed of a thermoplastic copolymer (usually ethylene vinyl acetate), and designed to fit over the upper teeth. There are three types of mouthguards: ready-made, mouth-formed "boil-and-bite," and custom-made. An effective mouthguard should be resilient, tear-resistant, properly fitting, and comfortable. It should also be easy to clean. A mouthguard should be cared for similarly to any oral appliance. Prior to and after each use, it should be rinsed with cold water or mouthrinse. It may also be brushed gently with a toothbrush. Mouthguards should be stored in a firm, closed container allowing for adequate airflow. High temperatures should be avoided to prevent distortion of the device. Mouthguards that are loose or have holes, are sharp, or causing irritation, should be replaced.[29,30]

It is necessary that mouthguards actually perform as required in order to keep teeth safe. Importantly, the ADA and the American National Standards Institute (ANSI) have developed a standard for Athletic Mouth Protectors and Materials. Very few OTC mouthguards meet these standards; ones that do will carry the ADA seal of acceptance.[30]

ORAL PAIN

Epidemiology

Dental pain is one of the most common reasons for OTC treatment for oral health.

Oral diseases, which range from cavities to gum disease to oral cancer, cause pain and disability for millions of Americans. Dental caries is one of the most common chronic conditions in the United States. Furthermore, more than 40% of adults have felt pain in their mouth in the last year. About 4 in 10 of US adults have some form of periodontal disease. In adults aged 65 and older, 68% have periodontal disease.[1] The 3 most common oral health issues seen in emergency departments are pain, trauma, and infection; 750,000 visits in the United States annually are for dental complaints.[31]

Etiology

Years of clinical and animal studies have indicated that the oral microbial flora is responsible for dental caries and periodontitis. Oral microbial communities are one of the more complex bacterial floras in the human body, with more than 700 different bacterial species identified from the human oral cavity.[32]

Dental caries often progresses without symptoms of the disease until a large area of the tooth is involved. Dental caries left untreated can result in bacterial infection of the pulp of a tooth, which can result in pulpal inflammation and eventual necrosis of the pulp tissue. An abscess, which is a collection of pus within the tissue, may develop as a result of pulpal infection, and is then called an apical abscess. If left unattended, the abscess can penetrate through the bone to involve the surrounding tissue structures. Once a dental abscess extends beyond the bone into the surrounding soft tissue, cellulitis develops.

Oral pain may also be caused by acute periodontal abscesses. Periodontal abscesses may be caused by an exacerbation of untreated chronic periodontitis, foreign body impaction into the tissue around a tooth, any alteration in the integrity of a tooth root (eg, fracture of root), or as a complication of treatment of periodontitis. They are characterized by swelling and purulent exudate of the affected area, mild discomfort to severe pain, and discomfort on palpation or percussion of the affected tooth. Periodontal abscesses may also advance to causing fever or malaise. Acute periodontal abscesses should be referred for urgent treatment by a dentist or oral health professional.

The aforementioned infections are polymicrobial, comprising of various facultative anaerobes, such as the viridans group streptococci and the *Streptococcus anginosus* group, and strict anaerobes, especially anaerobic cocci, *Prevotella* species, and *Fusobacterium* species.[33] One retrospective study found gram-positive cocci (*Streptococcus viridans*) to be the predominant bacteria, followed by gram-negative rods. *Staphylococcus aureus* is rarely involved in dental infections.[34]

Systemic involvement indicates a need for immediate intervention and treatment; patients should be referred to an oral healthcare professional or urgent care center for immediate care. Evidence of systemic involvement is listed in Table e16-7. Systemic antibiotics should only be prescribed when systemic involvement is evident. Apical abscesses are treated by removal of the infected pulp via root canal therapy or extraction of the infected tooth. Periodontal abscesses are addressed by cleaning the root surfaces of the involved teeth, establishing drainage of an abscess if present, extraction of teeth if necessary, and long-term follow-up to manage the periodontal disease.[35]

TABLE e16-7

Evidence of Systemic Infectious Involvement in Patients with Dental Caries and/or Periodontal Disease

- Swelling of the mouth and oral tissues
- Fever
- Malaise
- Cellulitis
- Difficulty breathing or swallowing

Data from Reference 35.

Treatment of Oral Pain

Patients may approach the pharmacist for recommendations concerning the treatment of oral pain, especially as many OTC options are available.

Oral Pain Relievers

④ The first-line therapy for the treatment of dental pain is nonsteroidal anti-inflammatory drugs (NSAIDs), acetaminophen, or a combination of both. Opioids are not recommended as first-line treatment for dental pain, and the ADA statement on opioid prescribing recommends providers consider NSAIDs as the first-line therapy for the treatment of acute dental pain. Recommendations also include educating patients on the benefits and risks of opioids, utilizing state prescription drug monitoring programs, and seeking continuing education on opioid prescribing.[36] ADA recommendations are based on evidence that NSAIDs, with or without acetaminophen, offer the best balance between efficacy for treating acute dental pain and avoiding potential harms of opioid use.[37]

Topical Pain Medications

Local Anesthetics

⑤ Benzocaine is a local anesthetic available in a wide variety of OTC products. For oral conditions, benzocaine is approved by the Food and Drug Administration (FDA) for toothache, ulcer of the mouth, and disorder of dental prosthesis causing pain. More than 500 products on the market contain benzocaine, including products intended for use on oral mucous membranes, as well as topical preparations for additional conditions, such as sunburn. Benzocaine is available OTC as an oral rinse, oral liquid with concentrations of 10% or 20%, oral dissolvable strips, oral gel, oral paste, oral swabs, and gum. Benzocaine blocks nerve conduction by inhibiting the depolarization of the neuronal membrane, thus blocking the initiation and conduction of nerve impulses. Depolarization is inhibited by a decrease in sodium ion permeability, which leads to a reversible stabilization of the neuronal membrane. Onset for toothache pain relief is 7 minutes and pain relief lasts 3 to 5 hours following topical application.[38]

Contraindications to the use of benzocaine include a hypersensitivity to benzocaine. Benzocaine is also contraindicated for teething pain or other indications in infants and children younger than 2 years of age due to the risk of methemoglobinemia. Other populations also have an increased risk of methemoglobinemia with benzocaine use, including patients with breathing problems, such as asthma, bronchitis, or emphysema, adults age 65 years or older, patients with heart disease, smokers, and those with genetic disorders such as glucose-6-phosphodiesterase deficiency. Large doses and large treatment areas, as well as the use on irritated or broken skin, increase the risk of systemic absorption and toxicity, although methemoglobinemia has been reported after a single benzocaine spray. Signs and symptoms of methemoglobinemia include pale, gray, or blue-colored skin, lips, and nails beds, shortness of breath, fatigue, confusion, headache, lightheadedness, and tachycardia. Symptoms may appear within minutes to 1 or 2 hours after use, and methemoglobinemia can occur with first application.[38]

Benzocaine-containing products should be applied according to package directions. Generally, patients are advised to apply product onto the affected area with cotton, cotton swab, or fingertip up to four times daily. When using the oral rinse, patients should swish with 15 mL up to four times daily and should be advised to spit, not swallow, remaining solution. The 20% benzocaine oral gel may also be used up to four times daily, applying a thin layer to the affected area. With all products, patients should be advised to use the product sparingly and no more than four times per day. The product should not be applied to broken or irritated skin, and no heat or occlusion should be used on the area. Patients should be educated on the signs and symptoms of methemoglobinemia and should seek medical care immediately at the first sign of symptoms.[38]

Magic Mouthwash

A prescription preparation, magic mouthwash is commonly compounded by the community, health-system, long-term care, or hospice pharmacist. Magic mouthwash is often prescribed for oral mucositis secondary to chemotherapy or radiation, as well as other conditions, such as canker sores. There is a lack of controlled, clinical studies demonstrating efficacy of magic mouthwash in treating oral mucositis, with some studies suggesting it no more effective than normal saline rinses. However, it is still commonly used in practice.[39]

Numerous formulations and recipes are available for magic mouthwash, and most institutions have their own institution-wide recipe for compounding. Ingredients commonly include topical local anesthetics, antihistamines for the local anesthetic effect, and a coating agent to enhance coverage of the ingredients to the affected oral tissue. Protectants, antifungals, antibiotics, and corticosteroids may also be included. According to a survey study of institutional pharmacies, the top five active ingredients used for magic mouthwash were diphenhydramine, viscous lidocaine, aluminum/magnesium hydroxide, nystatin, and corticosteroids. Many magic mouthwash formulations include equal parts viscous lidocaine 2%, diphenhydramine liquid, and aluminum/magnesium hydroxide antacid.[40] The inclusion of nystatin in magic mouthwash may not be appropriate as studies have not demonstrated efficacy of topical nystatin in preventing or treating oral fungal infections in patients with oral mucositis.[39] Similarly, the use corticosteroids is not supported by studies demonstrating efficacy, and risks may outweigh any benefits of use.[40]

Most formulations of magic mouthwash should be used every 4 to 6 hours. Ideally, irrigation of the mouth should be performed prior to applying topical medications in order to remove debris and allow for better coating of the oral tissue.[41] The solution should be held in the mouth for 1 to 2 minutes, and then patients should either swish and spit (if the solution contains lidocaine) or swallow. Lidocaine should not be swallowed as it may impact the gag reflex and can lead to systemic absorption. Patients should be advised to avoid eating or drinking for 30 minutes after use to prevent the removal of the anesthetic and coating agents, as well as to prevent trauma to the oral tissue when the mouth is numb.[39,40]

Concerns about the absorption of lidocaine have been raised, especially with possible absorption from damaged mucosas.[42] The use of compounded topical rinses should be carefully considered, including the cost of the product, potential adverse effects, and efficacy.[41] Adverse effects may include taste disturbances, burning or tingling of oral tissues, drowsiness, and gastrointestinal symptoms.[40] No formula of magic mouthwash has been shown to be superior to another, so patient preference should be the primary consideration. Regular assessment of the efficacy and acceptability of the compounded mouthwashes should be considered.[39]

TOOTH SENSITIVITY

Tooth sensitivity has a number of causes including dental caries, dentin hypersensitivity, tooth grinding, fractured teeth, and failing dental restorations. OTC products for sensitive teeth are indicated for dentin hypersensitivity, defined as the pain arising from exposed dentin. Dentin hypersensitivity typically occurs in response to chemical, thermal, tactile, or osmotic stimuli, and cannot be explained as arising from any other form of dental defect or pathology. It is classically short, sharp, and of rapid onset and short duration. Risk factors include gingival recession, periodontal disease, overenthusiastic brushing, an erosive diet, bulimia nervosa, and tooth wear.[43]

Dentin exposure is sometimes a result of physical wear of the enamel or erosion due to acidic breakdown. Physical wear of the enamel is caused by mechanisms such as tooth-to-tooth contact and the mechanical force from brushing. Erosion of enamel can be caused by chronic exposure to gastric acids, such as in gastric reflux and bulimia nervosa, and acidic foods and beverages (see Table e16-8).[44] Loss of enamel can be significant enough to warrant professional intervention and protection of teeth with fillings and restorations. Chronic enamel loss can be difficult to manage; treatment should be supervised by an oral healthcare professional. Teeth damaged due to caries or fracture may also be sensitive; thus, evaluation by an oral healthcare professional for proper diagnosis is important prior to beginning any home treatment regimen.

TABLE e16-8

Examples of Agents That Can Erode the Enamel of the Teeth

- Carbonated beverages
- Fruit juices
- Wine
- Fruits
- Gastric acid
- Tooth whitening products
- Abrasive toothpastes

Data from Reference 44.

Treatment for dentin hypersensitivity has historically involved either self-applied or professionally applied topical agents meant to alleviate symptoms. These agents are available in a variety of formulations and delivery mechanisms, such as toothpaste, gel, mouthrinse, and professionally applied medicaments. Potassium-containing toothpastes are the most widely used OTC treatments. Toothpastes should be applied with a soft-bristle toothbrush. Studies have shown that mouthwashes containing potassium nitrate and sodium fluoride can also reduce dentin hypersensitivity. However, sometimes more aggressive professional intervention is necessary if topical agents do not provide adequate relief. Treatment should also include avoidance of abrasive toothpastes and erosive agents, correction of misaligned teeth if they are contributing to the problem, and treatment of periodontal disease if present.[44] A variety of treatment agents available are noted in Table e16-9.[45]

TABLE e16-9

Agents Used in Tooth Desensitization

Active Ingredients	Types of Products	Availability of Evidence
Potassium salts (potassium nitrate, potassium chloride, potassium citrate)	Found in many OTC desensitizing toothpastes, also as aqueous solution or adhesive gel. Potassium ions reduce nerve excitability.	Evidence for use is low, but studies show positive effects of potassium nitrate and fluoride
Arginine	Found in toothpastes, powders, mouthrinse, and soft chews, as well as professionally applied paste	Evidence for use as a self-administered toothpaste is strong, and as a professionally applied treatment is fair
Strontium acetate	Available in OTC toothpastes	Moderate quality evidence supports use as a self-administered toothpaste
Fluorides (sodium fluoride, stannous fluoride)	Available in OTC and prescription toothpastes and gels. Decrease the permeability of dentin.	High-quality evidence, though limited, supports use as a self-administered toothpaste

Data from Reference 45.

TOOTH WHITENING

Tooth whitening has become a frequently requested dental procedure. In response to demand, many whitening products have become available. Whitening of a tooth can be achieved by bleaching or nonbleaching agents. Bleaching products help remove intrinsic and extrinsic stains, while nonbleaching agents work by physical or chemical action to remove extrinsic stains only. The efficacy of a whitening product is dependent upon its mechanism of action and the particular discoloration that is being treated.

Intrinsic staining can be attributed to factors such as antibiotics, like tetracyclines, high levels of fluoride resulting in fluorosis, exposed dentin from loss of enamel, demineralization or hypocalcification of the enamel, genetics, and developmental disorders resulting in enamel malformation. Extrinsic staining frequently results from environmental factors such as smoking; consumption of heavily pigmented foods and beverages such as coffee, tea, and wine; bacteria; metals such as iron or copper, and dental restorations that do not match the tooth color or amalgam fillings that cause grayish staining over time. Certain factors predispose children and adults to extrinsic stains, including enamel defects, salivary dysfunction, and poor oral hygiene.

Treatment

Bleaching and nonbleaching agents include OTC products, such as whitening pastes, films, gels, and rinses, as well as in-office products where more abrasive polishing pastes and/or highly concentrated bleaching agents are applied by oral healthcare professionals. The majority of bleaching products contain carbamide peroxide or hydrogen peroxide. Hydrogen peroxide is a weak acid with strong oxidizing properties that destroys the stain-causing substances by breaking apart the molecules. Carbamide peroxide breaks down on contact with water into hydrogen peroxide and urea.

Whitening toothpastes contain polishing or chemical agents that remove surface stains. They do this through abrasion, chemical chelation, or other nonbleaching actions. In-office bleaching products use hydrogen peroxide concentrations ranging from 25% to 40% and are sometimes used in conjunction with a light or laser. Though it has increased in popular use, light activation of bleaching agents seems to offer no benefit. Home-use products involve the application of a 10% to 20% carbamide peroxide-containing gel; due to the lower hydrogen peroxide concentration multiple treatments are typically necessary to achieve visible effects.[46] See Table e16-10 for a summary of the various treatment options.[47]

TABLE e16-10

Tooth Whitening Products

Teeth Whitening Systems	Whitening Agent	Application	Effectiveness
Whitening toothpastes	Abrasives, may contain carbamide peroxide, hydrogen peroxide	Brush on teeth, spit, rinse per manufacturer instructions	Effective on extrinsic stains, lighten by 1-2 shades
OTC whitening strips and gels	Peroxide-based gels	Apply adhesive strip to teeth or brush-on gel	Effective on extrinsic and some intrinsic stains, lighten by 1-2 shades
Whitening rinses	Oxygen sources such as hydrogen peroxide	Rinse for 30-60 seconds twice daily	Effective on extrinsic and some intrinsic stains, may take up to 3 months of use to lighten 1-2 shades
Tray-based tooth whiteners	Carbamide or hydrogen peroxide	Apply bleaching gel to inside of tray, insert and wear tray, time is variable depending on strength of bleaching agent	Effective on extrinsic and some intrinsic stains. Teeth may lighten 1-2 shades within a few days.
In-office whitening	Highly concentrated peroxide	Applied by dental health professional in office, usually with protection of soft tissues	Effective on extrinsic and some intrinsic stains. Whitening effects may be noticed immediately after one treatment and increase with more treatments.

Data from Reference 47.

Risks associated with tooth bleaching include increased tooth sensitivity and gingival irritation. In vitro studies have also demonstrated tooth erosion, increased tooth surface roughness, increased susceptibility to enamel demineralization, and pulpal damage. Aggressive bleaching can chemically react with composite fillings, glass ionomer cements, sealants, and ceramic crowns, reducing their integrity. When used according to manufacturer's instructions, hydrogen peroxide- and carbamide peroxide-based bleaching agents are safe and effective. However, individual conditions should be accounted for such as extent and cause of staining, previous dental restorations, tooth and tissue current health status, and other intraoral conditions. Supervision of one's bleaching strategy by an oral healthcare professional will reduce risks of adverse outcomes and optimize benefits of bleaching.[47]

CANKER SORES

Etiology/Pathophysiology

Canker sores, also referred to as aphthous stomatitis or aphthous ulcers, are among the most prevalent ulcerative conditions of the mouth. Canker sores generally appear as painful lesions on inner oral tissues, including the labial and buccal mucosa, as well as the, tongue.[48] Recurrent aphthous stomatitis (RAS) is the most common oral mucosal disease, affecting about 20% of patients.[49]

Unfortunately, the developmental mechanism of canker sores is not well understood. Genetics, emotional and physical stress, and certain nutritional deficiencies are amount the most commonly accepted etiologies.[48] However, immunological pathways, microbes, hormonal changes, and food sensitivities appear to play a precipitating role in the formation of canker sores as well.[50] In addition, chemical compounds and medications, including chemotherapy agents, NSAIDs, angiotensin converting enzyme inhibitors, angiotensin II receptor blockers, and SLS, have been implicated as causative agents.[48,50] Of these agents, NSAIDs are most often suspected medication-related cause, possibly related to a decrease in mucoprotective prostaglandins.[48]

Clinical Presentation

As mentioned previously, canker sores occur within the inner tissues of the mouth. They are further categorized by major, minor, and clusterform.[48]

Major aphthous ulcers are largest, over 1 cm in diameter with a healing time of 4 to 6 weeks. They may also result in scarring of the oral tissues. Clusterform are least common, often presenting in clusters of 10 to 100 ulcers at a single time. These ulcers may fuse together forming a larger ulcer irregular in shape. Clusterform ulcers typically take 10 to 14 days for healing.[48]

Minor ulcers are the most common type of aphthous ulcer, making up 80% of all types of canker sores. Minor ulcers are usually 4 to 6 mm in size, round to oval in shape, with a white to yellowish pseudomembrane surrounded by an erythematous ring.[48,50] They often heal within 7 to 10 days without leaving a scar.[48]

The lesions are generally painful and can even interfere with eating and/or speaking. Some patients report prodromal tingling or burning prior to the formation of the ulcer.[50] An example of a canker sore can be seen in Fig. e16-1.

FIGURE e16-1

Example of a canker sore. (*Source*: *MedlinePlus. Canker Sores.* https://medlineplus.gov/cankersores.html. *Accessed August 12, 2021.*)

Assessment

Fortunately, minor aphthous ulcers are typically self-limiting and do not require treatment or referral. However, appropriate assessment for self-care of canker sores depends on the severity of the condition, as well as the presence of signs and symptoms of underlying immune or mucocutaneous conditions.[48] Patients with large numbers of sores, sores greater than 5 mm in depth, slow healing canker sores, frequent episodes, significant discomfort, or the suspected presence of an underlying condition would benefit from referral to their primary care provider or otolaryngologist.[51]

Treatment

Treatment goals for canker sores include reducing pain, inflammation, and frequency of recurrent episodes. Patients should be educated to avoid substances that can worsen or trigger episodes and on ways to alleviate painful or bothersome symptoms. Patients would benefit from eliminating nuts, chocolate, acidic food and drink, salty and/or spicy foods, alcoholic and/or carbonated beverages from their diets. Patients may also benefit from avoiding oral products containing SLS.[49] These agents may trigger the formation or delay the healing of canker sores.

The current literature regarding the relationship between oral exposure to SLS and development of canker sores is unclear. A systematic review of double-blinded randomized controlled trials comparing SLS-containing and SLS-free dental cleaning products suggests that patients with RAS may benefit from choosing SLS-free oral health products. According to reviewers, SLS-free products reduced the number of ulcers, duration of ulcers, number of episodes, and average reported pain. However, this review only included 124 participants in total.[49] Larger well-designed trials are still necessary to strengthen the evidence linking SLS to RAS.

The use of topical products is most commonly recommended for the treatment of canker sores. Specifically, gel products are preferred due to their ease of application and appealing consistency. Patients should be instructed to dry the affected area prior to applying topical agents and avoid eating, drinking, and excessive speaking for at least 30 minutes following application. Classes of topical agents for the treatment of canker sores are listed in Table e16-11.[50–53]

TABLE e16-11

Topical Agents for Treatment of Canker Sores

Therapeutic Classes	Examples of Products	Clinical Pearls
Glucocorticoids	Clobetasol propionate cream, fluocinonide cream, triamcinolone acetonide cream	• Clobetasol and fluocinonide more effective than triamcinolone • Commercially available creams/ointments • Compounded rinses • Rinses preferred for diffuse area of lesions • Adverse effects: candidiasis • Prescription only
Antimicrobials	Tetracycline rinses, chlorhexidine rinse	• Tetracyclines reduce size, duration, and pain • Adverse effects: tooth staining • Prescription only
Anti-inflammatories	Amlexanox paste or patches, sucralfate liquid	• Amlexanox promotes healing, but does not reduce frequency of episodes • Prescription only
Tissue denaturants	Debacterol®	• Available as prefilled swabs for ease of use • Prescription only
Local anesthetics	Viscous lidocaine, benzocaine lozenges	• Lidocaine: prescription only • Benzocaine lozenges: OTC
Protectants	Sucralfate, mucoadhesive buccal patch	• Sucralfate: prescription only • Adhesive buccal patches: OTC
Combination products	Compounded magic mouthwash	• Typically made with equal parts viscous lidocaine 2%, aluminum/magnesium hydroxide antacid, and diphenhydramine liquid • Prescription only

Data from References 50–53.

Amlexanox (Aphthasol) is a prescription-only product available for the treatment of canker sores. The exact mechanism is unknown; however, it is believed amlexanox is anti-inflammatory, inhibiting the release of histamine and leukotrienes. Amlexanox is available as a paste or a patch. Patients should apply 0.25 in. (~0.6 cm) of the paste or one patch directly to the sore four times daily for 10 days. Up to three patches may be used at the same time if needed. Safety and efficacy have not been established in children younger than 12 years old. Those with a hypersensitivity to any of the ingredients of amlexanox should not use these products. Common adverse effects include stinging, irritation, or burning at the application site.[52]

Debacterol is the brand name of an additional topical agent indicated for the treatment of canker sores. This prescription-only product contains 50% sulfonated phenolics and 30% sulfuric acid. These chemicals act as tissue denaturants to alter the affected tissues and make them unsuitable to maintain the sores. Like other topical products, the affected area should be dried prior to administration. Once the tissue is dry, Debacterol should be applied directly to the lesion for at least 5 seconds using a cotton tipped applicator. It is not recommended to treat the same lesion with Debacterol more than once. Safety has not been determined in children under 12 years old or pregnant women. Stinging and local tissue irritation can occur during administration. Debacterol is available in a vial or prefilled single-use swabs.[53]

COLD SORES

Etiology/Pathophysiology

Cold sores, also known as oral herpes or herpes labialis, are the most common viral infections affecting the soft tissues of the mouth. Oral herpetic infections result from exposure to herpes simplex virus (HSV), most often herpes simplex type 1 (HSV-1).

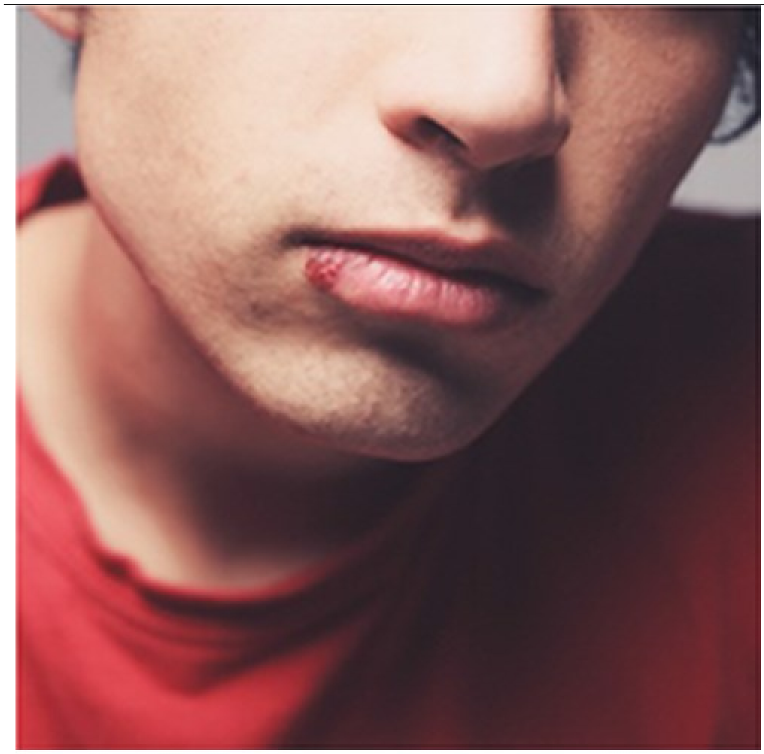
Generally, primary infections occur when HSV is transmitted during childhood, most individuals being exposed by age 5.[54] Transmission occurs by direct contact of the virus with mucous membranes or open skin. HSV enters and replicates within the neurons, where it lies latent after a primary infection.[55] Recurrent herpes labialis infections occur in up to 40% of those exposed to HSV, resulting from the reactivation of HSV. HSV can be reactivated by a variety of stressors, such as physical or emotional stress, fever, menstruation, and sun exposure.[55,56]

Clinical Presentation

Primary infection generally appears within 10 days following initial exposure to HSV, but it may take up to 3 weeks. Cold sore lesions begin on the lips as small vesicles, which rupture and fuse, forming a larger, painful, lesion. Intraoral lesions have a yellowish gray pseudomembrane, whereas extraoral lesions often appear crusty in nature.[54] Lesions also may be associated with localized prodromal symptoms such as tingling, burning, pain, or itching 24 to 48 hours prior to an outbreak.[51] Refusing food or drink may also be an indicator of an active HSV infection in children.[56] Healing typically begins within a few days, with complete healing up to 3 weeks for more severe cases.[51] An example of a cold sore can be seen in Fig. e16-2.

FIGURE e16-2

Example of a cold sore. *(Source: MedlinePlus. Cold Sores. https://medlineplus.gov/coldsores.html. Accessed August 12, 2021.)*



Source: Joseph T. DiPiro, Gary C. Yee, L. Michael Posey, Stuart T. Haines, Thomas D. Nolin, Vicki L. Ellingrod: *DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e*
Copyright © McGraw Hill. All rights reserved.

Assessment for Self-Care

Referral to the patient's primary care provider is likely necessary, as the most effective treatment options are available by prescription only. OTC options are available, but unfortunately these products are less effective than prescription treatments. Furthermore, patients suffering from frequent and/or severe reactivation infections would benefit from referral. Children and adolescents should be referred to a primary care provider as well.

Prevention

Patients should adopt preventive methods in order to inhibit formation or exacerbation of cold sores. Certain modifiable risk factors, such as stress, fatigue, sun exposure, and oral trauma, have been known to initiate the formation of cold.[55,56] Patients should be instructed to implement lifestyle modifications to reduce stress and fatigue. Patients should also avoid excessive sun exposure and use lip products with a sun protection factor of 15 or greater.

Treatment

Nonpharmacologic Methods

Symptoms, particularly pain and swelling, can be managed with application of cool and/or soothing materials. Patients may alleviate pain by eating foods such as ice cream or popsicles, applying cool washcloths, or gently icing the affected area. Additionally, patients should avoid spicy or acidic food and beverages as these have the potential to irritate existing sores and exacerbate associated symptoms.

Over-the-Counter Products

Topical docosanol (Abreva) is indicated for the treatment of cold sores and is available as a 10% cream in either a tube or a pump applicator.[57] Docosanol keeps HSV from fusing to the plasma membrane, preventing the virus from entering healthy skin cells, thereby suppressing viral replication.[58] When compared with placebo, docosanol shortens the time to complete healing by approximately 18 hours and alleviation of all symptoms by approximately 12 hours. This medication should be avoided by those allergic to any components of the preparation. OTC use is not approved for children younger than 12 years of age without direction from a healthcare provider.[57]

Adverse effects are rare (reported by fewer than 2% of patients) and limited to localized site reactions. Educate patients to wash hands before and after applying cream. Topical docosanol should be applied to the affected area and rubbed in gently at the first sign of symptoms, often prodromal burning or tingling, in order to ensure optimal results. Docosanol should be applied five times daily until the cold sore has healed.[57] In clinical trials, patients using docosanol is minimally effective over placebo, noting a decrease in duration of pain by less than 24 hours.[59] Overall, docosanol appears to be mildly effective, but is moderately expensive for the small size of the tube available.

Oral supplementation with lysine has been studied for the prevention of recurrent herpes labialis. Review of the current literature suggests recurrence rates can be decreased with daily doses exceeding 3 grams. These large doses were also associated with an improvement in patients' self-reported symptoms. However, studies focusing on lysine for prevention of recurrent cold sores often have small sample sizes and use lower doses of lysine (1.2 grams or less). Larger placebo-controlled trials with doses exceeding 3 grams per day are needed.[60]

Prescription Products

Topical acyclovir and penciclovir are available for the treatment of herpetic lesions. However, like topical docasanol, topical antivirals appear to be only mildly more effective than placebo.[59]

Oral antiviral agents, such as acyclovir and valacyclovir, are appropriate options for cases of recurrent oral herpes. Both agents are efficacious; however, valacyclovir would be the preferred agent. A systematic review and meta-analysis of the current literature notes that valacylovir was more effective in reducing the time to healing and resolution of pain compared to acyclovir.[61] Additionally, valacyclovir is more convenient in terms of dosing. Treatment with acyclovir requires three daily doses of 400 mg for a total of 5 to 10 days,[62] while valacyclovir requires only two doses of 2 g 12 h apart.[63] For additional information regarding mechanism of action and side effects, please refer to Chapter 135 "Sexually Transmitted Diseases."

XEROSTOMIA

Etiology/Pathophysiology

Xerostomia, commonly referred to as dry mouth, is one of the most prevalent oral conditions due to its numerous causes. Xerostomia affects approximately 22% of the population worldwide, most often affecting older individuals due to frequency of polypharmacy and a higher number of chronic medical conditions.[64]

Xerostomia is typically the result of impaired salivary secretion. Saliva promotes oral health by providing antimicrobial, physical, and chemical protection. It assists in chewing, swallowing, digestion, and speech formation. Saliva is largely composed of water, but also contains substances responsible for maintaining a neutral pH and healthy oral tissues.[64] Unfortunately, xerostomia is often overlooked, which is problematic given the important biological functions of saliva.

Xerostomia has a variety of causes. Acutely, dry mouth may simply be the result of dehydration of the oral tissues due to excessive mouth-breathing or systemic dehydration. Chronically, issues with the neuronal input and dysfunction of the salivary glands may cause dry mouth. Chronic xerostomia and/or salivary dysfunction is often the result of various chronic conditions, medications, and medical treatments (Table e16-12). These causes can have an additive effect and further exacerbate the condition. It is important to note that both OTC and prescription products may be to blame. Common medical conditions, including seasonal allergies, nasal congestion, motion sickness, and diarrhea, are often treated with OTC medications associated with dry mouth. Additionally, mental health disorders may be treated with medications associated with dry mouth and may also increase the awareness of the condition.[64]

TABLE e16-12

Causes of Xerostomia

Chronic Conditions	Medications	Medical Treatments
Sjögren's syndrome Graft vs host disease Lymphoma Diabetes Human immunodeficiency virus Methamphetamine abuse	Anticholinergics Antihistamines Angiotensin receptor blockers Angiotensin converting enzyme inhibitors Beta blockers Diuretics Opioids Antidepressants Antipsychotics	Radiation Chemotherapy

Data from Reference 64.

Clinical Presentation

Xerostomia has a number of different signs and symptoms depending on the severity of the condition. Primarily, it is characterized by a generalized feeling of dry oral tissues. Patients may also exhibit redness, peeling, and cracking in and around the mouth. Oral dryness may also result in frothy saliva and difficulty speaking, swallowing, or chewing. Additionally, patients may mention the need to continually sip liquids throughout the day and immediately upon waking.[64]

Complications

In addition to bothersome symptoms, xerostomia can cause a number of complications. Those suffering from xerostomia may notice difficulty speaking, chewing, and swallowing due to lack of necessary oral lubrication. Patients may experience halitosis or recurrent ulcers of the tongue and oral mucosa. Dry mouth increases the likelihood of dental caries, periodontitis, and thrush. Outside of the oral tissues, xerostomia may result in hoarseness, sore throat, and dry nasal passages. Some of these complications, like difficulty swallowing or halitosis can be resolved simply by alleviating dry mouth with methods outlined below. However, more severe complications, like dental caries and periodontitis, will not resolve with xerostomia treatment. Instead, these conditions must be treated by an oral health professional, so prevention is key. In order to prevent the development complications, adequate dental hygiene is vital, including daily brushing, regular use of fluoride, and routine dental visits.[64]

Assessment for Self-Care

Referral to a primary care or an oral health professional is determined by the cause and the severity of xerostomia. Cases resulting from the use of OTC medications can be appropriately managed by a pharmacist; however, patients and/or pharmacists would need to contact a healthcare professional with prescribing authority when prescription products have been identified as the cause.

Mild xerostomia can be appropriately treated with nonpharmacologic methods or OTC products. More severe cases of dry mouth, especially those causing additional complications, would warrant referral to the appropriate medical professional. Additionally, patients experiencing dry eyes along with dry mouth should be assessed for Sjögren's syndrome.[64]

Treatment

Nonpharmacologic Methods

Patients should ensure they are maintaining adequate hydration of the entire body, paying particular attention to the mouth, in order to establish sufficient lubrication of the oral tissues. This can be accomplished through frequent sipping of water, sucking on ice chips, and using a humidifier at night. Patients may also benefit from the use of sugar-free gum or candies in an attempt to stimulate salivary flow and alleviate dry mouth.[64]

Additionally, because tobacco use is commonly associated with dry mouth, patients would benefit from smoking cessation (see Chapter 45 "Chronic Obstructive Pulmonary Disease," and Chapter 86 "Substance-Related Disorders: Alcohol, Nicotine, and Caffeine" for more information on smoking cessation), or at the very least, reducing the number of cigarettes smoked each day. Like tobacco, caffeine use can also impede the formation of saliva; patients would benefit from reducing or eliminating caffeine-containing products from their diets.[64]

Over-the-Counter Products

Artificial saliva or saliva substitutes are designed to resemble biologic saliva, matching both its physical and chemical components. They are available as rinses, sprays, and gels. In order to alleviate the symptoms of xerostomia, artificial salivas generally contain ingredients that increase viscosity and act as oral lubricants, such as carboxymethylcellulose or xanthan gum. These ingredients help saliva substitutes adhere to the oral cavity for a longer period of time. Artificial saliva also contains sweeteners, such as sorbitol or xylitol, as they stimulate the production of saliva but are noncariogenic. Oral use of such sweeteners is generally regarded as safe. Adverse effects, such as diarrhea and flatulence, are associated with the consumption of large amounts of these sweeteners. Oral patches, chewing gum, and lozenges containing sorbitol or xylitol are also available. These products are not artificial saliva, and instead are intended only to stimulate saliva secretion. Table e16-13 contains a summary of directions for using OTC dry mouth products.[65–67,75–77]

TABLE e16-13

Directions for Use—Xerostomia Products

Product	Directions
Rinse	Swish 15 mL for 30 seconds, then spit; can be used up to five times a day
Spray	Apply to all affected tissues in the mouth; apply as needed
Gel	Place 0.5-in. (~1.5 cm) strip on tongue, spread evenly throughout the mouth
Toothpaste	Use a small amount to brush teeth at least twice daily
Patch	Place adhesive side on roof of mouth at least half way back, hold in place for at least 10 seconds
Chewing gum	Chew one piece as needed
Lozenge	Allow lozenge to dissolve in mouth as needed

Data from References 65–67.

While artificial saliva products rapidly alleviate symptoms, they have a short duration of action (~15 minutes). More viscous products, like gels, may have a longer duration of action compared to rinses and sprays. While the wetting effect of artificial saliva does not last long, these products can be used frequently and are relatively inexpensive, easy to use, and safe. As regards product selection, the ADA recommends using products with its Seal of Acceptance, as these products have been deemed both safe and effective.[64]

Prescription Products

Pilocarpine and cevimeline are two prescription products available to treat xerostomia. Pilocarpine is FDA-approved to treat xerostomia as a result of radiation and Sjögren's syndrome,[68] while cevimeline is only approved to treat xerostomia from Sjögren's syndrome.[69] Both medications are cholinergic agonists, working to increase secretion from the salivary gland.[68,69] Because they work by increasing secretion, pilocarpine and cevimeline treatment would only be appropriate in patients who have maintained at least some function of their salivary gland(s). Recommended dosing for pilocarpine is 5 mg by mouth four times daily,[68] and for cevimeline is 30 mg by mouth three times daily.[69] These medications are generally well tolerated. Their adverse effects include cholinergic-associated effects, such as sweating, indigestion, nausea, and rhinitis.[68,69]

TRAUMA

⑨ Traumatic dental injuries (TDIs) occur frequently in children and young adults, comprising 5% of all injuries for which people seek treatment.[70] A 12-year review of the literature reports that 25% of all school children experience dental trauma and that 33% of adults have experienced trauma to the permanent dentition.[71] Luxation injuries, or displacement of the tooth from its position, are the most common TDIs in the primary dentition, whereas crown fractures are more commonly reported for the permanent dentition.[72]

Any type of traumatic dental injury warrants referral to a dental professional. However, a few dental injuries involving the permanent teeth require immediate action, as well as referral to a dental professional who can determine whether or not the injury is an emergency and recommend appropriate treatment. For displaced primary teeth, consult a dental professional. Primary teeth that are completely displaced should not be reimplanted due to the risk of damaging developing permanent teeth.[73]

If a permanent tooth is partially displaced, one should attempt to replace and reposition the tooth within the socket using finger pressure and barrier protection. The patient should bite down on a sterile gauze pad to temporarily splint the tooth. If the tooth is entirely displaced, it should be located and verified that it is whole, and then gently rinsed with saline solution for no more than 10 seconds. Attempts should be made to reimplant the tooth within 5 minutes by observing the placement of adjacent teeth for proper placement.[73] Both of these situations are classified as dental emergencies, and the patient should be immediately referred to an oral healthcare provider or emergency facility.

Teeth that cannot be replaced should be stored in physiologic medium (eg, Hank's Balanced Salt Solution), saline, or milk, in order to prevent the tooth from drying out and to prevent the death of cells during transport of the tooth.[74–76] When an appropriate solution is not available, patients should place the tooth in the mouth between the cheeks and gums.[73]

PEDIATRICS

Oral health is a vital component of health for infants and children. Community and health-system pharmacists may be approached with questions regarding oral health in infants and children. The AAP recommends that primary care providers conduct oral health risk assessments on children at every well-child visit, and that children begin seeing an oral health professional within 6 months after the first tooth appears or no later than 1 year of age. Risk factors for caries in infants and children include sleeping with a bottle and continual use of a sippy cup with liquids other than water. Dietary counseling should emphasize reducing exposure to sugars. Additionally, caregiver oral health impacts the oral health of children, including by the transmission of *Streptococcus mutans*, a risk factor for dental caries. Thus, good caregiver oral health should be encouraged and emphasized.[77]

Fluoride

Dental caries is the most common chronic condition in children in the United States, making caries prevention an important focus.[77] Fluoride is effective in preventing dental caries in both systemic and topical dosage forms.[15] Systemic fluoride exerts its effects both through incorporation into teeth before eruption, as well as through an additional topical effect from absorbed fluoride present in the saliva. The anticariogenic property of fluoride is predominantly through its topical effects, which is why fluoride remains effective in children and adults whose permanent teeth have erupted. Drinking fluoridated water also has topical effects as the teeth are exposed to fluoride when drinking.[15] For more information on fluoride, please refer to section "Oral Health Prevention and Maintenance" earlier in this chapter.

Children may encounter fluoride from multiple sources including fluoridated drinking water, fluoride toothpaste, fluoride varnish, and dietary fluoride supplements. Fluoridated drinking water is a common source of fluoride supplementation. Indeed, the Centers for Disease Control and Prevention (CDC) considers water fluoridation one of the 10 most important public health measures of the 21st century.[78] The US Public Health Service recommends an optimal fluoride concentration of 0.7 mg/L for drinking water. This recommendation considers both the positive caries prevention effects, as well as the potential for fluorosis. Ultimately, the decision of whether to fluoridate community drinking water rests with state and local governments.[79] Other sources of fluoride include beverages, such as soda and juice, infant formula, prepared foods, topical fluoride varnishes, fluoride toothpaste, and oral fluoride supplementation.[80]

Fluorosis of permanent teeth results from an excess of cumulative fluoride intake during tooth development when tooth enamel is being mineralized. Fluorosis risk is influenced by both dose and frequency of fluoride ingestion, and is possible in children younger than 8 years with the period of most susceptibility between 15 and 30 months of age. Mild fluorosis causes minor cosmetic discoloration of the teeth that may include small white spots or streaks (Fig. e16-3). Mild fluorosis is not readily noticeable to casual observation. Moderate and severe fluorosis may include cosmetic and structural concerns but are uncommon in the United States.[80] In the United States, greater than 99% of fluorosis cases are classified as mild. Still, the risk of fluorosis must be compared to the advantages of fluoride on oral health when making decisions concerning the use of fluoride-containing products and supplements.[81]

FIGURE e16-3

Oral **Fluoride** Supplementation

⑩ The ADA guidelines on fluoride supplementation offer recommendations aimed at finding the optimal balance between the benefits and risks of fluoride use. Oral fluoride supplementation reduces the incidence of caries in both primary and permanent teeth in children. However, as described above, dietary fluoride also increases the risk of fluorosis when given during tooth development.[82]

Clinical recommendations from the ADA and AAPD (American Academy of Pediatric Dentists) for the use of dietary fluoride supplementation is based both on risk for dental caries and fluoride concentration in drinking water. Dietary fluoride supplementation is recommended for children at high risk for caries and whose primary source of drinking water is deficient in fluoride.[82,83] Note that recommendations from the US Preventive Services Task Force (USPSTF) vary is that these only consider fluoride concentration of drinking water.[81] Healthcare providers can contact health departments at the local, county, or state level to determine fluoride levels in drinking water. For patients with water from individual wells, certified laboratories can conduct a fluoride test. There are many dental caries risk assessments available, and healthcare providers should assess caries risk on a regular basis.[82] Note that even if children drink primarily bottled water, fluoride is still consumed through tap water used in cooking and toothbrushing.[83]

Dosing of dietary fluoride supplements are based on patient age and fluoride concentration of drinking water. Supplementation is only recommended when fluoride concentration of drinking water is below 0.6 ppm and the patient is at a high risk of caries.[82] This recommendation is echoed in the AAPD guidelines on fluoride therapy,[83] the USPSTF Recommendation Statement[81], and the AAP.[80] Fluoride dosing recommendations are listed in Table e16-

14. Once permanent teeth have erupted, the benefits of fluoride supplement result from the direct topical effect of the supplement, as well as the indirect topical effect from increased concentration of fluoride in the saliva.[82]

TABLE e16-14

Recommended ADA Dietary Fluoride Supplement Dosing Schedule for Children at High Risk of Developing Caries

Age	Fluoride Concentration in Drinking Water (parts per million)		
	<0.3	0.3-0.6	>0.6
Birth to 6 months	None	None	None
6 months-3 years	0.25 mg/d	None	None
3-6 years	0.5 mg/d	0.25 mg/d	None
6-16 years	1 mg/d	0.5 mg/d	None

Data from Reference 82.

Fluoride supplements should be kept out of the reach of children as fluoride can be toxic in higher concentrations. Fluoride supplements must be used daily for maximum effect. It is recommended that patients chew or suck fluoride tablets for 1 to 2 minutes prior to swallowing in order to maximize the topical effect of the fluoride.[82] Liquid formulations are available, but chewable products are preferred because of increased topical exposure to fluoride.[80]

Fluoride Varnish

The AAP recommends that primary care providers apply fluoride varnish for early childhood caries prevention and bases these recommendations on those by the AAPD and ADA.[80] Fluoride varnish is concentrated topical fluoride applied to the teeth and allowed to set. This allows for a prolonged therapeutic effect. The AAPD recognizes evidence from controlled trials demonstrating the efficacy of professionally applied topical fluoride treatments in reducing dental caries in children.[83] The USPSTF recommends fluoride varnish for all infants and children at the age of tooth eruption, and under the Patient Protection and Affordable Care Act, this preventive service should be covered without cost-sharing.[80]

Fluoride Toothpaste

Fluoride toothpaste consistently demonstrates efficacy in reducing dental caries in children, and toothbrushing should begin with the first eruption of primary teeth. Regular use with adult supervision is most effective. Children should be taught to spit instead of swallowing toothpaste to reduce systemic exposure to fluoride, but children younger than 6 years of age are much more likely to swallow toothpaste. Children younger than 3 years of age should use a smear or rice-sized amount of fluoridated toothpaste. Fluoride consumption associated with swallowing toothpaste can increase the risk for fluorosis. Children 3 to 6 years old should use a pea-sized amount. Parents should be advised to supervise toothbrushing, especially for children under 8 years of age, and to store toothpaste out of reach of young children. It is recommended to advise parents to teach children to spit without water, as this lessens the amount of toothpaste swallowed and leaves more fluoride available in the saliva.[80]

Teething

Etiology and Clinical Presentation

The process of tooth eruption, in which teeth move through the mucosa into the oral cavity, is commonly referred to as teething. This can be associated with increased irritability, crying, drooling, and chewing, although many children may have no symptoms or apparent difficulties during tooth eruption.[84] Symptoms may include local irritation including swelling and tenderness in the gums.[85,86] A meta-analysis found teething signs and symptoms present in 70.5% of infants aged 0 to 36 months, with the most prevalent symptoms being gingival irritation (87%), irritability (68%), drooling (56%).[87] Parents often associate many additional symptoms with teething, including fever, decreased oral intake, and diarrhea. Interestingly, these beliefs are consistent worldwide. Some studies do show a small rise in body temperature during tooth eruption, but this rise is not characterized as fever. Studies do not support teething causing diarrhea, decreased liquid intake, or other symptoms, such as rash or vomiting. Primary teeth eruption usually begins between 4 and 7 months of age, beginning with the central incisors, which are the two lower front teeth. Most children have a complete set of 20 primary teeth by 30 months of age.[84]

Assessment

Teething may be stressful for parents, and parents may not feel confident in treating teething symptoms.[87] Symptoms such as crying, fever, and ear pain may be incorrectly ascribed to teething, so education on the common symptoms of teething is useful in determining the proper level of care. Parents may approach a community pharmacist or other primary care provider asking about recommendations for treating teething pain; while products are available and are advertised for teething, those containing benzocaine are contraindicated in infants and children younger than 2 years of age.[85]

Treatment

Nonpharmacologic Methods

Pediatric guidelines recommend the use of chilled rings, often made of firm rubber, for infants to chew or gum. Biting applies pressure to the gums, giving the infant relief of teething discomfort. Some teething toys filled with liquid can be chilled. The cold causes vasoconstriction, thus decreasing inflammation. However, frozen teething toys or rings should be avoided as the extreme cold can cause damage to the gums.[86] Liquid-filled toys should not be sterilized in extreme temperatures, such as in the dishwasher or boiling, because of concerns that this may cause leakage of the liquid. There are some reports of contaminated liquid in fluid-filled teethers.[84]

Complementary and Alternative Medicine

Amber teething necklaces may be used by parents to decrease pain associated with teething. When worn by the infant, manufacturers claim that small amounts of oil are released into the skin, thus reducing pain, drooling, and inflammation. However, there is no scientific evidence to support the claims. The AAP recommends that infants should not wear any jewelry, as there is a risk of strangulation and choking.[88]

Pharmacologic Agents

Oral Analgesics

The AAP recommends oral analgesics for pain associated with teething if needed. Before 6 months of age, only acetaminophen is recommended. However, after 6 months of age either acetaminophen or ibuprofen is appropriate, with further recommendations to receive dosing instructions based on infant weight from child’s healthcare provider.[86]

Topical Anesthetics

Topical anesthetics, such as benzocaine, are not recommended due to potential toxicity.[86] Benzocaine is found in many OTC teething gels and teething products. The FDA released a safety announcement warning that the use of benzocaine in OTC gels or liquids applied to the gums or mouth is associated with methoglobinemia, a rare but potentially fatal condition. The FDA has asked manufacturers to stop marketing OTC oral drug products for teething in infants and children younger than 2 years of age. Benzocaine is now contraindicated for children under 2 years of age, so parents should not use these products in this population. Brand names of teething products containing benzocaine include Baby Orajel.[89]

In studies, the majority of reported cases of methoglobinemia occurred with the use of benzocaine for teething in children under 2 years of age. Symptoms develop within minutes to hours after use of benzocaine. Signs and symptoms include pale, gray or blue colored skin, lips, and nail beds; headache, lightheadedness, shortness of breath, nausea, fatigue, or tachycardia.[89]

The AAP states that teething gels are not effective as excessive salivation often washes gels off gums quickly. There is also concern that benzocaine may numb the throat and interfere with the infant's ability to swallow.[86] Oral viscous lidocaine should also not be used for the treatment of teething pain in children for these same concerns.[89]

CONCLUSION

The entire healthcare team—including pharmacists and other primary care providers—plays an important role in promoting oral health. The AAP recommends that primary healthcare providers play a larger role in oral health by measures such as conducting regular caries risk assessments, offering counseling on diet and oral hygiene, and applying fluoride varnish for infants and children.[77,80] Pharmacy can support this greater focus on integrating oral health into primary care. Given their accessibility, community pharmacists are well-placed to be advocates for good oral healthcare and maintenance. All pharmacists should be familiar with oral health basics and the numerous OTC products available in order to play a vital role in educating patients and improving public health.

SELF-ASSESSMENT QUESTIONS

1. Which of the following is TRUE regarding the selection of a toothbrush?

   A. Soft, flat bristles are most effective for plaque removal.

   B. Multilevel or angled bristles improve plaque removal.

   C. Toothbrushes should be replaced every 3 to 4 months.

   D. Both B and C are correct.

2. Fluoride strengthens teeth by:

   A. Inhibiting the demineralization of enamel

   B. Enhancing the remineralization of decalcified enamel

   C. Incorporating into the apatite crystal of the bone and teeth

   D. All of the above.

3. A patient enters your pharmacy complaining of sore gums. Upon examination, you determine he is likely suffering from denture stomatitis. He tells you he cleans his dentures daily, wears them continuously, and uses a denture adhesive. What is the most likely cause of his denture stomatitis?

   A. Cleaning his dentures daily

   B. Wearing his dentures continuously

C. Occasional use of a denture adhesive

D. None of the above—he is caring for his dentures appropriately

4. Which of the following is TRUE regarding dental injuries in sport?

A. Mouthguards are only necessary for contact sports as dental injuries do not occur in other sports.

B. Mouthguards should be placed in boiling water after each use to prevent the spread of infection.

C. An improperly fitted mouthguard may be associated with noncompliance.

D. All of the above alternatives are correct.

5. The following symptoms may indicate that a dental infection has systemic involvement:

A. Tenderness of the tooth

B. Yellowing of the tooth

C. Xerostomia

D. Fever

6. Dental caries:

A. May be transmitted from person to person, such as from caregiver to child.

B. Result in similar symptoms as periodontal disease.

C. Is treated with antibiotics, as bacteria are a large causative factor.

D. All of the above alternatives are correct.

7. A patient approaches with a question regarding an OTC tooth whitening product. She wonders what the difference is between a whitening toothpaste and OTC whitening strips, and which would be more effective. Which of the following would be an appropriate point of education?

A. Whitening strips contain abrasives as a whitening agent.

B. She can expect OTC whitening strips to be effective against coffee stains, and lighten teeth by 1 to 2 shades.

C. Staining from the use of tetracyclines can always be treated with OTC products.

D. Light-based activation of bleaching agents offers additional benefits over the use of OTC products alone.

8. A patient comes to your pharmacy complaining of recurrent canker sores. Which of the following questions would be appropriate to ask when assessing the patient?

A. What types of food/drink do you typically consume?

B. Have you been exposed to herpes simplex virus type 1?

C. Do you have Sjögren’s syndrome?

D. None of the above would be appropriate questions.

9. A patient comes to your pharmacy complaining of a sore on her mouth. As you are speaking with the patient, you notice that the sore is a crusty lesion on her lip. She mentions that she has had similar sores before and that they often begin with a burning or tingling sensation. It is likely this

patient is suffering from a:

A. Dental abscess.

B. Canker sore.

C. Cold sore.

D. None of the above alternatives is correct.

10. At the pharmacy, a patient approaches you about the treatment options for cold sores. Which of the following statements could you tell him?

A. Docosanol cream is available without a prescription, but it is only mildly effective.

B. Eating cold foods (like popsicles and ice cream) may temporarily relieve cold sore pain.

C. The most effective treatment options are prescription-only products.

D. All of the above alternatives are correct.

11. Which of the following would **NOT** help alleviate the symptoms of dry mouth?

A. Smoking cessation

B. Maintaining adequate hydration

C. Chewing sugar-free gum

D. Frequent sips of coffee

12. You see a patient running into the pharmacy with his 7-year-old son. The child tripped in the parking lot and knocked out one of his teeth. The father is in a panic and asks what he should do. Which of the following questions should you ask?

A. Did you locate the tooth, and is it whole or broken?

B. Is the displaced tooth a permanent or primary tooth?

C. How many minutes ago did this occur?

D. All of the above alternatives are correct.

13. Which of the following is true regarding fluoride?

A. Only systemic fluoride is effective in preventing tooth decay, and so all fluoride exposure must occur before permanent teeth have erupted.

B. In adults, systemic fluoride may exert anticariogenic effects through increased concentration of fluoride in the saliva.

C. Almost all bottled waters contain concentrations of fluoride similar to fluoridated drinking water and can be considered an adequate source of fluoride.

D. Fluoride toothpaste should not be used in children under 6 years of age.

14. Oral fluoride supplements are most likely indicated for which of the following patients?

A. A 36-year-old with a high risk of caries and drinking water with fluoride concentration of 0.2 ppm

B. A 4-month-old baby with a moderate risk of caries who is entirely formula-fed with nonfluoridated water

C. A 6-year-old with low risk of caries and drinking water with fluoride concentration of 0.1 ppm

D. A 10-year-old with high risk of caries and drinking water with fluoride concentration of 0.4 ppm

15. A mother approaches with a question regarding teething pain in her 8-month-old infant. She is holding a brand-name teething product containing benzocaine, and wonders whether this would be effective. What would be appropriate advice?

A. A benzocaine-containing product may not be effective, but amber teething necklaces are recommended by pediatric organizations.

B. This product may not be effective, but oral analgesics should always be used for teething pain as nonpharmacologic methods of treatment are not effective.

C. The benzocaine-containing product should be avoided, and oral acetaminophen or ibuprofen may be used if necessary for teething pain.

D. The benzocaine-containing product is safe and is preferred to prevent the use of unnecessary oral analgesics.

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D.** Multilayered or angled bristles are more effective for plaque removal than flat bristles. It is recommended that toothbrushes or toothbrush heads are replaced every 3 to 4 months to ensure adequate plaque removal. See subsection “Toothbrushing” under section “Oral Health Prevention and Maintenance” for more information.

2. **D.** Fluoride inhibits the demineralization of enamel and enhances the remineralization of enamel as it is incorporated into the apatite crystal of bone and teeth. See subsection “Toothpaste” under section “Oral Health Prevention and Maintenance” for more information.

3. **B.** Regular denture maintenance includes daily cleaning by soaking and brushing with an effective, nonabrasive denture cleanser. Dentures should not be worn continuously in order to minimize the risk of developing denture stomatitis. The effects of long-term use of dental adhesives have not been established, but the occasional use is likely not associated with the development of denture stomatitis. See subsection “Denture Care” under section “Oral Health Prevention and Maintenance” for more information.

4. **C.** While contact sports have inherent dental injury risk, dental injuries are prevalent in noncontact sports and activities as well. Mouthguards should be rinsed with cold water or mouthrinse and may be gently brushed with a toothbrush. Placing them in boiling water may damage the appliance. Studies have shown that dental injury rates do not differ between types of mouthguards. However, ill-fitting or uncomfortable mouthguards are associated with decreased compliance, so patients should be advised to choose a comfortable appliance. See subsection “Athletic Mouthguards” under section “Oral Health Prevention and Maintenance” for more information.

5. **D.** Symptoms that indicate possible systemic infection include swelling, fever, malaise, cellulitis, or difficulty breathing or swallowing. See subsection “Etiology” under section “Oral Pain” for more information.

6. **A.** Dental caries is a chronic disease that may be transmitted from caregiver to child. This is why good caregiver oral health is vital for child oral health. Symptoms are different than periodontal disease, with the focus on the tooth rather than the gums. While bacteria have been implicated with dental caries, treatment does not usually include antibiotics. See subsection “Etiology” under section “Oral Pain” and “Pediatrics.”

7. **B.** OTC products are effective for extrinsic stains, such as from food or drinks, and typically lighten teeth by 1 to 2 shades. Whitening toothpastes contain abrasives, while strips do not. Light activation of bleaching agents does not seem to offer additional benefits over the use of the bleaching agent alone. Intrinsic staining, such as from tetracyclines, can often only be treated by an oral health professional. See subsection “Treatment” under section “Tooth Whitening” for more information.

8. **A.** Certain types of foods and drinks, such as acidic and/or spicy foods and carbonated beverages, can trigger the development of canker sores and potentially prolong the duration of the episode. Discussing the patient’s diet may help identify food or beverages to avoid to prevent frequent episodes. See subsection “Treatment” under section “Canker Sores” for more information.

9. **C.** While dental abscesses, cold sores, and canker sores all affect the oral tissues and often cause pain, there are some distinct differences among these conditions. Cold sores develop as crusty lesions on the lips. Canker sores present as pseudomembranous lesions inside the oral cavity. A dental

abscess is characterized by swelling and purulent exudate of the tissues around the affected tooth. See subsection “Clinical Presentation” under section “Cold Sores” for more information.

10. **D.** All of these statements are true and would be appropriate to tell a patient regarding cold sore treatment. See subsection “Treatment” under section “Cold Sores” for more information.

11. **D.** Frequent sips of coffee would not help the symptoms of dry mouth as caffeine-containing beverages can often make dry mouth worse. All the other options would be appropriate for the relief of dry mouth. See subsection “Treatment” under section “Xerostomia” section for more information.

12. **D.** A displaced tooth should be located if possible and assessed whether it is whole or broken. It is recommended that an attempt should be made to replace and reposition a displaced tooth within the socket. However, this is only for permanent teeth, and primary teeth should not be reimplanted. Attempts to reimplant the tooth should be made within 5 minutes of injury. See section “Trauma” for more information.

13. **B.** Systemic fluoride increases fluoride concentration of saliva, providing anticariogenic effects in adults and children with permanent teeth. Bottled waters often do not contain adequate amounts of fluoride. Fluoride toothpaste is recommended for small children, but only a smear for children under 3 and a pea-sized amount in children 3 to 6 years old to prevent fluorosis. See subsection “Fluoride” under section “Pediatrics” for more information.

14. **D.** Oral dietary fluoride supplements are only indicated for children ages 6 months to 16 years who are at a high risk for caries. They would not be indicated for a child at low risk of caries, even if drinking water fluoride concentration is low. They are not indicated for adults, or infants under 6 months. See subsection “Oral Fluoride Supplementation” under section “Pediatrics” for more information.

15. **C.** Infants may have only mild discomfort with teething, and pediatric guidelines recommend the use of chilled rings for infants to chew to relieve pain. If necessary, oral acetaminophen or ibuprofen could be used in an 8-month-old infant with no medical conditions. Products containing topical benzocaine are contraindicated in children under 2 because of the risk of methoglobinemia. Amber teething necklaces are not recommended because of the risk of strangulation or choking. See “Treatment” under subsection “Teething” (section “Pediatrics”) for more information.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e >

Chapter e17: Skin Care and Minor Dermatologic Conditions

Rebecca M. Law; Howard I. Maibach

KEY CONCEPTS

KEY CONCEPTS

① The skin is the largest organ of the human body. It performs vital functions such as (a) protecting the body against injury, physical agents, and ultraviolet radiation; (b) regulating body temperature; (c) preventing dehydration, thus helping to maintain fluid balance; (d) acting as a sense organ; and (e) acting as an outpost for immune surveillance. Skin also has a role in vitamin D production and absorption.

② Age-related factors affect the epidermis, dermis, and subcutis. Pediatric skin is thinner, which enhances topical drug absorption and potential drug toxicities. Neonates, particularly premature neonates, are especially susceptible due to an incomplete skin barrier. Skin of older adults is drier, thinner, and more friable, which may predispose them to external insults and loss of the skin barrier function.

③ Examination of a patient's skin involves assessing skin color (degree of pigmentation, pallor, carotenemia, jaundice), skin temperature (warm, cool, clammy), skin surface characteristics (dryness, seborrhea, turgor, excessive or reduced sweating, texture), and the degree of photoaging.

④ Signs that a mole (nevus) may be dysplastic include: size >5 mm, irregular shape, variable/different pigmentation, indistinct borders; and they may be totally flat or flat with a central elevation.

⑤ Skin hydration is especially important for people with dry skin conditions. This involves an appropriate daily skin care routine and adequate daily fluid intake.

⑥ Management of diaper dermatitis includes frequent diaper changes, air drying (removing the diaper for as long as practical), gentle cleansing (preferably with nonsoap cleansers and lukewarm water), and the use of barriers such as zinc oxide 40% ointment. After healing, a barrier such as zinc oxide 10% should be used with each diaper change as prophylaxis.

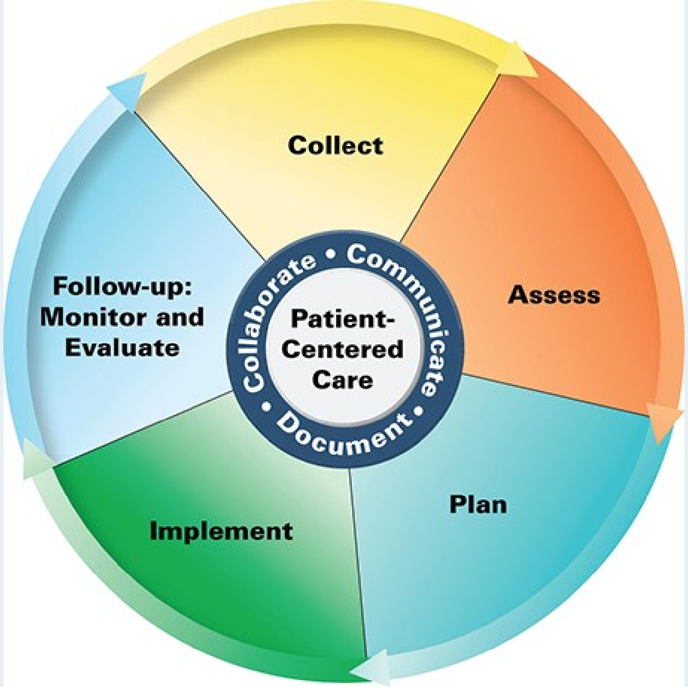
⑦ Due to the many negative effects and skin disorders relating to sun damage, sun protection at all times is critical, and this should be emphasized to patients, whether they are on medications with photosensitivity potential or not. Sun protection includes sunscreens, sun avoidance, shading, long sleeve clothing, and wide brim hats or hats with a flap that covers the ears and neck. Sunscreens should always be used except in infants <6 months of age.

PATIENT CARE PROCESS

Three Patient Care Process boxes have been included in this chapter to enhance learning as follows:

1. Patient Care Process 1: Nevi
2. Patient Care Process 2: Diaper dermatitis
3. Patient Care Process 3: Sunburn

Patient Care Process for Nevi



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Collaborate • Communicate • Document •
Patient-Centered Care

The image shows the five fundamental steps included in The Pharmacist's Care Process endorsed by the Joint Commission for Pharmacy Practitioners (2014). The tagline of this process reads collaborate, communicate, and document. The five fundamental steps listed here are collect, assess, plan, implement, and follow-up: monitor and evaluate. All these steps are listed in a circular block diagram.

Collect

- Patient characteristics (eg, age, sex, pregnancy status)
- Patient medical history (personal and family) for skin cancer or melanoma Size and shape of skin lesions of concern
- Recent changes in the appearance of lesions
- During patient interactions, be alert for the presence of moles or other lesions that appear to be suspicious

Assess

- Appearance of lesions (concerning features include size >5 mm, irregular shape, variable pigmentation, indistinct borders) (see Fig. e17-7)

Plan*

- Advise patients with suspicious lesions to seek dermatologic or other medical evaluation (see **Chapter e121**, “Drug-Induced Dermatologic Disorders” for more information on skin cancers)
- For those who report having lesions evaluated previously, advise dermatologic or other medical evaluation if the appearance has changed

Implement*

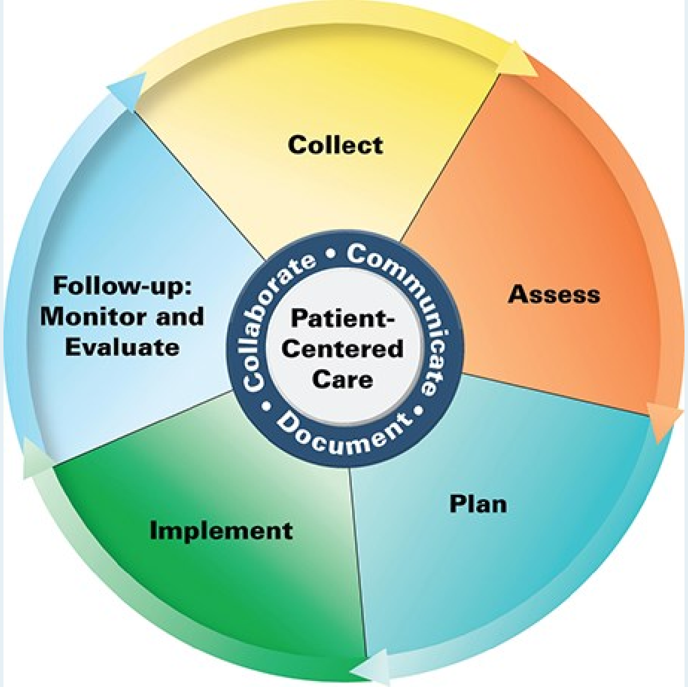
- Not applicable

Follow-up: Monitor and Evaluate

- Contact patient and/or health professional (if privacy concerns allow) to confirm dermatologic or other medical evaluations

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

Patient Care Process for Diaper Dermatitis



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Age and sex of child/adult/elderly person
- Past history of diaper dermatitis and any complications
- Appearance of current rash and area affected
- Presence of signs of infection or severe irritation (eg, vesicles, erosions, pus)

Assess

- Parent/caregiver/patient (if adult) affect/concern about condition
- Ability to pay for medical care

Plan[*]

- Refer for medical evaluation if the condition is severe or signs of infection or severe irritation are present (see Chapter 119, "Atopic Dermatitis," Chapter 133, "Skin and Soft Tissue Infections," and Chapter 143, "Superficial Fungal Infections" for related information)
- If diaper dermatitis is not severe or infected, recommend nonpharmacologic and over-the-counter (OTC) interventions: change diapers frequently and preferably as soon as soiling occurs; air dry skin during a diaper change and for as long as practicable afterward; use nonsoap cleansers with lukewarm water to provide gentle cleaning; apply a 40% zinc oxide product during each diaper change until rash resolves; once the rash is resolved, apply a 10% zinc oxide product during diaper changes for prevention.

- Avoid the use of talcum powders due to the risk of inhalation

Implement[*]

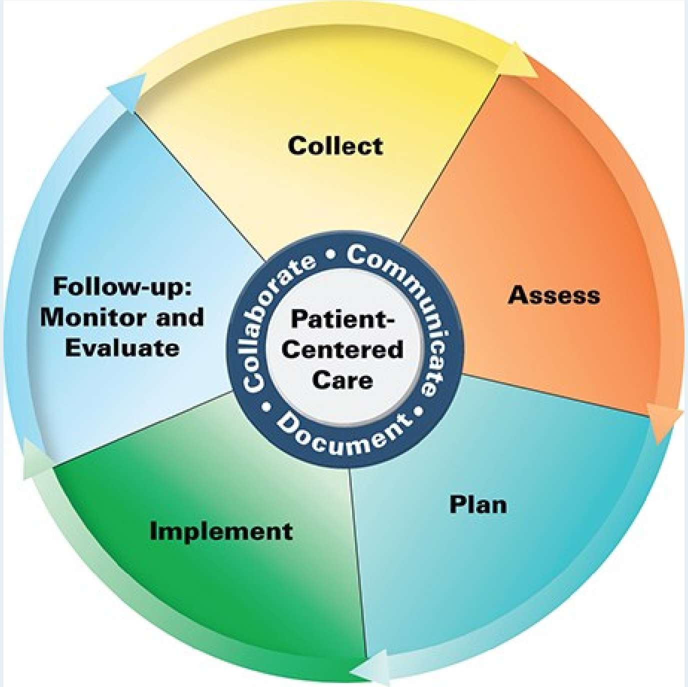
- Provide parent/caregiver/patient education regarding all elements of a treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence

Follow-up: Monitor and Evaluate

- Contact parent/caregiver/patient to confirm resolution
- Refer for pediatric or medical evaluation if the condition has not been resolved

[*] *Collaborate with patient, caregivers, and other healthcare professionals.*

Patient Care Process for Sunburn



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient characteristics (eg, age, sex, pregnancy)
- Patient medical history (personal and family)
- Patient description of the history of burn, subjective complaints of pain, and other symptoms
- Severity of burn
- Signs of dehydration
- Symptoms of systemic involvement (eg, fever, confusion, weakness, shivering, headache, seizures)
- Symptoms of heat stroke (eg, dry, hot flushed skin with no sweating, rapid pulse, confusion, dizziness, seizures)

Assess

- Need for medical evaluation because of symptoms, possibility of advanced burn, presence of systemic symptoms, ability of the patient to manage burn, dehydration, or other complications
- Ability/willingness to pay for medical treatment options
- Emotional concerns

Plan*

- Refer for medical evaluation and care if the burn is severe, complications are present, or patient/caregiver is concerned about the condition
- Recommend therapies for rehydration as needed (see **Chapter e21**, “Pediatrics: Oral Nutrition and Rehydration of Infants and Children” and **Chapter 164**, “Assessment of Nutrition Status and Nutrition Requirements”)
- To relieve pain, itch, and swelling associated with burn, recommend the application of cool compresses to burn; cool showers several times daily; drinking adequate fluids; and staying out of the sun for 1 week
- As indicated, OTC measures can be implemented: oral analgesics for pain; moisturizers for dryness and lubrication; pramoxine lotion, calamine, and colloidal oatmeal for soothing; topical diclofenac gel; oral diphenhydramine for itch and swelling
- Topical anesthetics are *not* recommended because of the increased risk of sensitization

Implement

- Provide patient education regarding all elements of the treatment plan
- Use motivational interviewing and coaching strategies to maximize adherence
- Provide information about prevention of future sunburns, including use of sunscreens on regular basis, proper application, and reapplication during periods of sun exposure, sweating, and exposure to water

Follow-up: Monitor and Evaluate

- Contact patient/caregiver in 2 to 3 days to assess resolution of sunburn
- Reinforce preventive measures in future interactions with the sun

******Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

Review the anatomy and physiology of the skin as described in this chapter of *Pharmacotherapy*. Audiovisual presentations of this material are available online, including a video on the components of the skin (https://medlineplus.gov/ency/anatomyvideos/000029.htm) from the National Library of Medicine.

INTRODUCTION

The novelist Deen Ferrell has equated skin to life: “Life is too much like skin. It molds to the core of who you are and whether you dress it up, or try to keep busy so you don't have to think about it, it doesn't go away."[1] Too often, we neglect to think about our skin or pay attention to changes on our skin that don't go away. We allow our skin to get so dry it itches, cracks, and hurts. We ignore bumps and lesions on our skin because they are often painless and always present, so we do not notice when slow or subtle changes occur, which may be innocuous—or life threatening. It is easy to grow accustomed to something that is always there. We need to pay attention and teach our patients to pay attention.

① Although not commonly thought of as such, skin is a vital organ with important functions. In fact, skin is the human body's largest organ, with an average surface area of about 1.8 m^2.[2] The organ system that includes the skin is known as *the integumentary system*.

The human skin consists of an outer epidermis and an inner dermis, with subcutaneous fat. The epidermis (in four layers) primarily provides protection from the environment and performs a critical barrier function—keeping in water and other vital substances and keeping out foreign elements. The dermis is a connective tissue layer that primarily provides resiliency and support for various skin structures and appendages such as sweat glands, sebaceous glands, hair, and nails. It also provides support for nerves and blood vessels. The subcutis (subcutaneous tissue) is a fatty layer below the dermis that helps to maintain the body temperature stable and protect bones and muscles from damage. It also allows nerves and blood vessels from the dermis to pass through and reach the muscles (Fig. e17-1). See the "Structure and Functions of the Skin" section for further discussion.

FIGURE e17-1

Layers and structures of the skin. (*Original artwork courtesy of Rebecca Law, ©2018 by R Law, all rights reserved.*)

Because the skin surface is readily visible, changes that are slow or subtle often go unnoticed. Slowly enlarging and evolving moles or dry skin conditions can go undetected even though such changes can be life threatening in some cases (eg, malignancy). Health professionals who have direct contact with patients should be able to distinguish between common self-treatable skin lesions and common skin lesions that must be seen and treated professionally such as melanoma and squamous cell carcinoma (for more discussion, see Chapter e121). Patients should be reminded that they need to be vigilant and report suspicious or changing lesions to their health care professionals.

Skin and soft tissue infections are discussed in Chapter 133, and drug-induced skin reactions, contact dermatitis, photoaging, skin cancers, acne, psoriasis, and atopic dermatitis in Chapters 117 to e121.

EPIDEMIOLOGY AND BURDEN OF SKIN DISEASES

It is difficult to estimate the burden of skin disease since the term is broad and somewhat ambiguous. In addition to disorders with primarily skin manifestations such as atopic dermatitis, diseases can have multiorgan system involvement plus skin manifestations (eg, lupus erythematosus), and these conditions may not be treated by dermatologists. Furthermore, some skin disorders primarily involving the skin are usually not treated by dermatologists (eg, second- or third-degree burns) and are often excluded from estimates of the burden of skin disease. In addition, some skin conditions treated by dermatologists are not classified as such in some systems (eg, malignant melanoma is classified as an oncologic disorder by the International Classification of Diseases [ICD] and by the National Institutes of Health [NIH], although mortality data for skin diseases typically will include malignant melanoma, which is covered in Chapter 162, “Melanoma”).[3]

Skin disease-related mortality is low in comparison to other types of illnesses such as cardiovascular diseases (MI, stroke), infectious diseases (HIV/AIDS), and cancers. Thus, the burden of skin disease is often overlooked or underemphasized in healthcare resource planning both nationally and globally.[4]

STRUCTURE AND FUNCTIONS OF THE SKIN

The integumentary system comprises the epidermis, dermis, and subcutaneous fat (also known as subcutis, see Fig. e17-1). The epidermis, derived from ectoderm, is further divided into four layers: *stratum basale* (basal layer), *stratum spinosum* (prickle cell layer), *stratum granulosum* (granular layer), and *stratum corneum* (horny layer). The *stratum corneum* is the outermost layer of skin and primarily is responsible for the barrier function. The epidermis is thick on the palms and soles and thin on other parts of the body, with some content variations. For example, the palms and soles contain eccrine glands but lack sebaceous glands, which are found almost everywhere else in the skin, with the highest concentration on the face and trunk. Sebaceous glands and small hair follicles together form pilosebaceous units, which originate in the dermis and have follicular ducts extending through the epidermis to the skin surface. Sebaceous glands produce sebum, a lipid-like substance.[2] (Increased production by sebaceous glands is partially responsible for acne.[5]) As mentioned earlier, the dermis provides support for sweat glands, sebaceous glands, hair, nails, nerves, and blood vessels. Subcutaneous tissue below the dermis allows nerves and blood vessels to pass through and reach the muscles (Fig. e17-1).

Epidermal cells—keratinocytes—produce keratin, a protein network that gives epithelial cells resilience to mechanical stress. Keratinocytes begin at the *stratum basale* as box-shaped basal cells. As the cells mature, they migrate toward the surface, elongating and flattening as they divide and differentiate, ending as corneocytes in the *stratum corneum.* Corneocytes are flattened keratinocytes containing keratin tonofibrils (filaments composed of keratin and keratohyalin granules). They are often termed *dead* because they do not contain nuclei and are incapable of mitosis. Each cell covers a much larger surface area as a corneocyte compared with its basal cell origin. Overlapping corneocytes provide for the skin barrier.[2] (Note that abnormal keratinocyte activity accounts for some skin diseases. For example, psoriasis is associated with increased keratinocyte cell turnover, and acne is partially caused by abnormal keratin.[5])

Melanocytes, pigment-producing cells in the *stratum basale*, produce melanin, a yellow–brown/black pigment. Melanin granules are spread out into a protective layer in the *stratum corneum*, reducing ultraviolet (UV) penetration into the skin. UV radiation causes human skin to increase both melanin production and keratinocyte proliferation as a protective effort.[2]

The skin surface is normally covered with a hydrolipid film composed of sweat, oils (sebaceous lipids and free fatty acids), corneocytes, protein decomposition products, and transepidermal water. Some of these are natural moisturizing factors that help the skin retain water. Thus, the hydrolipid film is a permeability barrier that keeps the skin supple.[2]

Because of the presence of lactic acid and amino acids from sweat, free fatty acids from sebum, and amino acids from shedding corneocytes, human skin is normally acidic, generally with a pH of 4 to 6. Bacteria thrive in an alkaline environment. As a result, the skin also functions as a protective acid mantle against invasion by pathogenic bacteria and fungi.[2]

The dermis, derived from mesoderm, is a much thicker layer that contains nerve endings and blood vessels. It is made of collagen and elastin, which provide support for various skin structures and appendages. Eccrine (sweat) glands, hair follicles, sebaceous glands, and arrector pili muscles originate in the dermis. Apocrine (sweat) glands have a secretory coiled portion at the junction of the dermis and subcutis and a straight portion that inserts and secretes into the hair follicle. Subcutis or subcutaneous tissue (adipose tissue with nerves and blood vessels) lies beneath the dermis.[2]

Skin is also involved in regulating body temperature, preventing dehydration, acting as a sense organ, and playing a role in vitamin D production and absorption.

AGE-RELATED SKIN DIFFERENCES

② Age-related changes in the structure and functions of the epidermis and dermis are important.

In general, pediatric skin is thinner, possibly allowing for enhanced topical drug absorption in both the rate and amount of drug absorbed. In addition, the permeability barrier function of the skin is likely not intact in the preterm baby—as genesis of the permeability barrier starts in the last quarter of gestation and only finishes just before term.[6] These factors increase the potential for drug toxicities in neonates, infants, and children. Increased topical absorption and toxicity have been reported with the use of rubbing alcohol, boric acid powders, and hexachlorophene emulsions and soaps in infants and young children. Even drugs that are not normally used topically may be systemically absorbed. For example, a theophylline gel (17 mg spread over an area 2 cm in diameter) applied to the abdomens of premature infants produced therapeutic serum theophylline concentrations.[7]

This example also illustrates the difference in the body surface area (BSA) to body weight (BW) ratio between infants and adults. An infant's BSA:BW ratio may be twice that of an adult's, resulting in higher systemic bioavailability for topical doses applied based on the surface area, even when the dose has been adjusted for BSA differences (ie, dose based on infant BSA as a percent of adult BSA).[6]

Well-hydrated, unbroken skin provides maximal protection against microbial invaders and noxious substances. Aged skin tends to be drier, thinner, and more friable, which increases its susceptibility to external insults and loss of the skin barrier function. In addition, the healing time after skin injury may be prolonged in aged skin.

Skin differences based on race and ethnicity have been reported with respect to the thickness of the stratum corneum, skin responses to topical drugs and environmental agents, and aging. These can be considered in cases of reactions to irritants such as sodium lauryl sulfate, occupational dermatitis, “stripping” of the skin when cellophane tape is removed, and pigmentation, wrinkling, and skin laxity during aging.[8–11] The interested reader is directed to the 2017 book *Dermatoanthropology of Ethnic Skin and Hair* edited by Vashi and Maibach.[12]

SKIN ASSESSMENT

③ In simple terms, examination of a patient's skin involves assessing skin color (degree of pigmentation, pallor, carotenemia, jaundice), skin temperature (warm, cool, clammy), skin surface characteristics (dryness, seborrhea, turgor, excessive or reduced sweating, texture), and the degree of photoaging.[13]

Lesion Assessment

The appearance of skin lesions can provide clues as to their causes. Where are the lesions located? Lesions may be localized (isolated), grouped, regional, generalized, symmetrical, or located in sun-exposed areas, flexural areas, extensor extremities, intertriginous areas, etc.[13] What do the lesions look like? Lesions may be categorized as macules (Fig. e17-2), papules (Fig. e17-3), nodules (Fig. e17-4), blisters (Fig. e17-5), or plaque and lichenification (Fig. e17-6). There are also other types of raised lesions (eg, horn—conical column of hyperkeratosis over a papule), depressed lesions (eg, ulcer, striae, sinus), fluid-filled lesions (eg, furuncle), and purpura/vascular lesions (eg, purpura, telangiectasia), and others. The interested reader is directed to *Fitzpatrick's Dermatology in General Medicine*.[13]

FIGURE e17-2

Macules are circumscribed, flat lesions of any shape or size that differ from surrounding skin because of their color. (*A*) They may be the result of hyperpigmentation (*a*), hypopigmentation, dermal pigmentation (*b*), vascular abnormalities, capillary dilation (erythema) (*c*), or purpura (*d*). (*B*) The clinical appearance of a drug reaction that has produced an eruption consisting of multiple, well-defined red macules of varying size that blanch upon pressure (diascopy) and are thus a result of inflammatory vasodilation. *(Reproduced with permission from Stewart MI, et al. The structure of skin lesions and fundamentals of diagnosis. In: Freedberg IM, Eisen AZ, Wolff K, et al., eds. Fitzpatrick's Dermatology in General Medicine, 6th ed. New York: McGraw Hill; 2003.)*

FIGURE e17-3

Papules are small, solid, elevated lesions that are usually <1 cm in diameter. The major portion of a papule projects above the plane of the surrounding skin. (*A*) They may result, for example, from metabolic deposits in the dermis (*a*), from localized dermal cellular infiltrates (*b*), and from localized hyperplasia of cellular elements in the dermis and epidermis (*c*). Papules with scaling are referred to as papulosquamous lesions, as in psoriasis (see Chapter 80, “Headache Disorders”). (*B*) Clinical examples of papules. The examples are two well-defined and dome-shaped papules of firm consistency and brownish color, which are dermal melanocytic nevi. (*C*) Multiple, well-defined, and coalescing papules of varying size are seen. Their violaceous color, glistening surface, and flat tops are characteristic of lichen planus. *(Reproduced with permission from Stewart MI, et al. The structure of skin lesions and fundamentals of diagnosis. In: Freedberg IM, Eisen AZ, Wolff K, et al., eds. Fitzpatrick's Dermatology in General Medicine, 6th ed. New York: McGraw Hill; 2003:18.)*

FIGURE e17-4

Nodules are palpable, solid, round, or ellipsoidal lesions. Depth of involvement or substantive palpability, rather than diameter, differentiates a nodule from a papule. (*A*) Nodules may extend into the dermis or subcutaneous tissue (*a*) or be located in the epidermis (*b*). (*B*) A well-defined, firm nodule with a smooth and glistening surface through which telangiectasia (dilated capillaries) can be seen; there is central crusting indicating tissue breakdown and thus incipient ulceration (nodular basal cell carcinoma). (*C*) Multiple nodules of varying size can be seen (melanoma metastases). *(Reproduced, with permission, from Stewart MI, et al. The structure of skin lesions and fundamentals of diagnosis. In: Freedberg IM, Eisen AZ, Wolff K,* *et al., eds. Fitzpatrick's Dermatology in General Medicine, 6th ed. New York: McGraw Hill; 2003.)*

FIGURE e17-5

Vesicles and bullae are the technical terms for blisters. While vesicles are circumscribed lesions that contain fluids, bullae are vesicles that are larger than 0.5 cm in diameter. (*A*) While subcorneal vesicles (*a*) result from fluid accumulation just below the stratum corneum, spongiotic vesicles (*b*) result from intercellular edema. (*B*) Multiple translucent subcorneal vesicles are extremely fragile, collapse easily, and thus lead to crusting (arrows). These lesions are staphylococcal impetigo. *(Reproduced, with permission, from Stewart MI, et al. The structure of skin lesions and fundamentals of diagnosis. In: Freedberg IM, Eisen AZ, Wolff K, et al., eds. Fitzpatrick's Dermatology in General Medicine, 6th ed. New York: McGraw Hill; 2003.)*

FIGURE e17-6

(*A*) Plaque is a mesa-like elevation that occupies a relatively large surface area compared with its height above the skin surface. (*B*) Well-defined, reddish, scaling plaques can coalesce to cover large areas of the back and buttocks, with some regression in the center as is common in psoriasis (see Chapter 118). (*C*) Lichenification, a thickening of the skin and accentuation of skin, can result from repeated rubbing. It develops frequently in patients with atopy and occurs in eczematous dermatitis and other conditions associated with pruritus. Lesions of lichenification are not as well-defined as most plaques and often show signs of scratching, such as excoriations and crusts. *(A & B: Reproduced, with permission, from Stewart MI, et al. The structure of skin lesions and fundamentals of diagnosis. In: Freedberg IM, Eisen AZ, Wolf K, et al., eds. Fitzpatrick's Dermatology in General Medicine, 6th ed. New York: McGraw-Hill, 2003; C: Reproduced, with permission, from Amit G, et al. Structure of Skin Lesions and Fundamentals of Clinical Diagnosis. In: Wolf K, et al., eds. Fitzpatrick's Dermatology in General Medicine, 7th ed. New York: McGraw Hill; 2008.)*

Some skin conditions may be manifested by more than one type of lesion. For example, patients with acne vulgaris may present with macules, papules, nodules, or a combination of these. Another example is psoriasis—the most common type is plaque psoriasis noted by discrete, well-defined plaques; however, there are other types of psoriasis such as guttate or erythrodermic with varying lesions. Wheals developing as a result of a drug reaction may present as papules or plaques. In contrast, some skin conditions present with a characteristic lesion. For example, lichenification is a thickening of the skin usually caused by chronic rubbing or scratching and can be seen in patients with chronic pruritus or atopic dermatitis.

Moles (Nevi)

Freckles and moles are common—sometimes a particularly well-placed mole may be seen as a beauty mark. The dark side is that atypical moles, also known as dysplastic nevi, are risk markers for melanoma.

④ Signs that a mole (nevus) may be dysplastic include: size >5 mm, irregular shape, variable/different pigmentation, indistinct borders, and they may be totally flat or flat with a central elevation[14] (Fig. e17-7).

FIGURE e17-7

Dysplastic nevi. (Reproduced with permission from Grichnik JM, et al. Atypical (dysplastic) melanocytic nevi. In: Goldsmith LA, Katz SI, Gilchrest BA, et al., eds. Fitzpatrick's Dermatology in General Medicine. 8th ed. New York, NY: McGraw Hill; 2012.)

It must be emphasized that dysplastic nevi—which are often readily identifiable—are precursors *only* for melanomas. Other types of skin cancers may be much less obvious, and may even appear benign. For example, Merkel cell carcinoma—which occurs mostly in sun-exposed areas of older men—may look benign or acneiform in more than 50% of cases, with many lesions so minor that they do not appear to warrant a diagnostic biopsy; unfortunately, the mortality rate is high (close to 50%) since there are often metastases at the time of diagnosis. For a brief discussion of skin cancers, refer to Chapter e121.

SKIN CARE BASICS

It should not be surprising that skin health is related to overall health. Exercise and adequate sleep along with maintaining a healthy, well-balanced diet are key factors. Ample daily fluid intake and regular use of moisturizers are important for skin hydration.

Our skin normally contains 10% to 20% water by weight. If skin hydration drops below 10%, the following may occur: (1) the stratum corneum becomes brittle and may crack more easily; (2) mild inflammation and impaired cell maturation may occur; (3) foreign invaders may penetrate the skin more easily; and (4) chapping may result.

For skin cleansing, soapless cleansers may be preferable to soap because they may cause less irritation. Repeated and frequent exposure to soap or other cleansers that cause cumulative irritation (eg, with surfactants and emulsifiers) can result in irritant contact dermatitis. Cleansing too frequently can cause dry skin.

Hydration and Moisturizers

⑤ Skin hydration is especially important for people with dry skin conditions. Ideally though, an appropriate daily skin care routine should be followed by everyone. This should preferably include the following activities[15]:

- Using fragrance-free moisturizers *ad lib* throughout the day. Large quantities can be used—especially in those with dry skin conditions such as atopic dermatitis. There are no firm recommendations regarding the appropriate amount or dosing frequency of moisturizers.
- Bathing in lukewarm water (never hot) for about 5 minutes once daily. Adding a capful of emulsifying oil may help the body retain moisture; baths are better than showers for moisturizing. Avoid prolonged hot bathing.
- After bathing or showering, the skin should be lightly towel dried (pat to dry, avoid rubbing or brisk drying).[16]
- Applying moisturizer (fragrance-free) while the skin is still moist or slightly damp (within 3 minutes of towel drying).[17] Some fragrance-free moisturizers include Aveeno Moisture Cream, Cetaphil, Neutrogena Hand Cream, and Vanicream. Lotions may be used on the scalp and other hairy areas and for mild dryness on the face, trunk, and limbs; creams are more occlusive than lotions; ointments are the most occlusive and can be used for drier, thicker, or more scaly areas.[17] Occlusive moisturizers are the best since they capture transepidermal water loss by providing a layer of oil on the skin surface, increasing the moisture content of the stratum corneum.
- Using nonsoap skin cleansers may cause less skin irritation. Lipid-free and fragrance-free skin cleansers may be particularly advantageous (eg, Cetaphil Gentle Skin Cleanser, Free and Clear Liquid Cleanser, Spectro Jel for sensitive problem-prone skin). Aquanil, Dove, Neutrogena, and pHisoderm sensitive-skin products have also been recommended as low-irritant products, and some are lipid-free.
- Minimizing the use of astringents and alcohol-containing cosmetics or cleansing products including lotions, swabs, and wipes (they may be drying).

Nutrition

Malnourishment can cause a patient to become immunocompromised, which may adversely affect the ability of the skin to act as a barrier. Nutritional deficiencies can cause skin problems, including dry skin. For example, essential fatty acid deficiency can cause a dry, scaly rash as well as other issues including poor wound healing, hair loss, and biochemical abnormalities (eg, hyperlipidemia, elevated triene:tetraene ratio, elevated liver function tests).[18]

Scents and Fragrances

There are approximately 2,500 fragrance chemicals. Why so many? Most consumer products often need several specific fragrances to mask the odor of ingredients in the product—to enhance consumer appeal. Fragrance ingredients are either natural or synthetic.

As health professionals, it is important to be aware of the allergic potential of fragrances and scents. In particular, there is an important distinction between *fragrance-free* and *unscented* products. A *fragrance-free* product does not contain synthetic chemicals whereas an *unscented* product only has the fragrance portion of the product removed (ie, it may still contain synthetic chemicals, and these may be allergenic).[19] Thus, where available, fragrance-free products are preferred.

Of the 2,500 chemicals, only 26 are considered sufficiently common allergens, and if products containing them were sold in the European Union (EU), those chemicals would have to be identified and listed as ingredients on the product labels. There are another 20 chemicals that are under consideration by the EU for listing but are not yet required. Unfortunately, elsewhere in the world—including in the United States and Canada—there are no requirements for identification and labeling.

Label identification would allow a consumer to avoid products containing known allergens. It is possible for patients to be patch tested to identify their specific allergens as these 46 chemicals are commercially available for patch-testing purposes. However, determining the clinical relevance of a positive patch test requires considerable judgment and is often demanding.[20] An exception would be the person who uses a fine fragrance (perfume) and develops a reaction—the product to avoid would be easily identifiable since the reaction would occur at the exact spots (eg, behind the ears) where the perfume was applied. However, perfumes are usually composed of more than one ingredient, complicating identification.

Absorption Through the Skin: General Principles and Relevant Factors

When it comes to percutaneous absorption, human skin is a complex series of diffusion barriers.[21] This affects drug absorption through the skin (Fig. e17-8).[21]

FIGURE e17-8

The percutaneous absorption process had been described as a 10-step (10-factor) process[6] and later expanded to 15 factors,[22,23] with additional factors still being delineated (Table e17-1).

TABLE e17-1

Steps in the Process of Percutaneous Absorption

1. Release from vehicle: Varies with solubility in vehicle, concentration, pH, and other factors	
2. Kinetics of skin penetration: Influenced by anatomical site, degree of occlusion, intrinsic skin condition, age of patient, concentration of dosing solution, surface area dosed, frequency of dosing, p postabortion parameters, and other factors	
3. Excretion kinetics	
4. Tissue disposition	
5. Substantivity to skin	
6. Wash effects: Wash resistance and wash enhancement	
7. Rub effects: Rub resistance and rub enhancement	
8. Transfer: To skin, clothing, and inanimate surfaces	
9. Exfoliation	
10. Volatility	
11. Binding: All layers	
12. Anatomical pathways	
13. Lateral spread	
14. Vascular perfusion	
15. Cutaneous metabolism	

Data from Reference 22.

Key points related to percutaneous absorption include the following:

1. Absorption rate varies at different anatomical skin sites—in general, faster if hair follicles are present in large numbers and slower if the stratum corneum is thick.[22]
2. In regard to absorption of environmental toxins, the head and face are areas of higher skin absorption.[22]
3. The outer layer of skin is lipid in nature; thus, lipophilic drugs and lipophilic environmental toxins are absorbed faster.[22]
4. The partition coefficient of a drug or environmental toxin is a useful predictor of drug absorption through the skin.[22]
5. Drugs given systemically can be excreted via the eccrine gland and this is based on their partition coefficients and their p*K*s. Basic drugs with high

partition coefficients and p*K*s close to sweat pH are more readily excreted and can accumulate on the skin in significant amounts.[22]

6. The stratum corneum can act as a "reservoir" for topical drugs and environmental toxins. Hence, they are not always easily removed by conventional "decontamination" methods (ie, soap and water).[22]
7. Vehicles and occlusion affect topical drug absorption. For a given thickness of stratum corneum at a specific anatomical site, a drug's stratum corneum:vehicle partition coefficient determines its absorption rate.[22]

DRY SKIN—ISSUES AND CARE

Dry skin, also known as *xerosis*, is a common condition associated with various factors including environment (winter, dry climates), occupation (jobs that involve frequent handwashing such as nursing or hair styling), aging, or malnutrition. It is a nonspecific symptom for many systemic and dermatologic diseases. Appropriate skin care to maximize skin hydration as discussed above is especially important for those with dry skin.

Extremely dry skin can be accompanied by inflammation and is known as *dermatitis*. Atopic dermatitis and psoriasis are dermatologic conditions with extremely dry skin that must be managed proactively. Skin cracks and fissures can occur, increasing the likelihood of secondary bacterial infections (most commonly *Staphylococcus*). Refer to Chapter 119, "Atopic Dermatitis," and Chapter 118, "Psoriasis," for further discussion.

Pruritus

When dry skin is accompanied by itching, also known as *pruritus*, this needs to be appropriately managed. Be cognizant that pruritus is a hallmark symptom of atopic dermatitis. Nonpharmacologic measures such as cotton gloves for infants and children to minimize scratching/excoriations are useful. Sedating antihistamines such as diphenhydramine may reduce nighttime scratching and promote more restful sleep when taken at bedtime.[17,24] These may be useful for patients with significant sleep disruption due to itch.

Topical antihistamines should be avoided due to their potentially irritant or sensitizing effects. However, prescription-requiring topical calcineurin inhibitors tacrolimus and pimecrolimus are effective anti-itch agents when there is inflammation. Management of pruritus is discussed in detail in Chapter 119.

DIAPER DERMATITIS

Diaper dermatitis, more commonly known as diaper rash, is traditionally seen in infants, although the condition may also be seen in adults who wear diapers for incontinence. It is an acute inflammatory dermatitis affecting the buttocks, genital, and perineum regions that are covered by the diaper. The rash is erythematous, and severe rashes may have vesicles or oozing erosions. The rash may be secondarily infected by *Candida* species (most commonly *Candida albicans*) and present with confluent red plaques, papules, and pustules, with early maceration of anal mucosa and perianal skin. The rash generally spares inguinal skin folds except for *Candida* diaper rashes, which almost always involve the inguinal folds.

⑥ Management of diaper dermatitis includes frequent diaper changes, air drying (removing the diaper for as long as practical), gentle cleansing (preferably with nonsoap cleansers and lukewarm water), and the use of barriers. Zinc oxide has astringent and absorbent properties and provides an effective barrier. Formulations with higher zinc oxide concentrations (40%) can be used for treatment.

After the diaper rash is resolved, lower concentration zinc oxide products (10%) should be used regularly with each diaper change for prophylaxis. Petrolatum also provides a water-impermeable barrier but has no absorbent ability and may trap moisture; thus, these products are less suitable. Commercial diaper wipes containing fragrance or alcohol should be avoided. Talc (talcum powder) should be avoided due to the risk of inhalation—corn starch is a safer alternative.

Patients with candidal (yeast) diaper rash should be treated with a topical antifungal agent which is then covered by a barrier product—always apply the antifungal agent first. Imidazoles are the treatment of choice for this type of diaper rash. After the rash subsides, the antifungal agent should be stopped and the barrier product continued to prevent a recurrence.

In severe inflammatory diaper rashes, a low-potency topical corticosteroid (hydrocortisone 0.5%-1%) may be used for short periods of 1 to 2 weeks.

If the rash does not respond after a week of recommended therapies, if there is increase in pain or inflammation during therapy, if deep ulcerations are present (ie, severe rashes), or if systemic signs or symptoms are present (eg, fever, diarrhea, skin lesions elsewhere in the body), there should be a referral for pediatric or medical evaluation. (For related information, see other chapters as noted in the patient care process below.)

SUN DAMAGE—ISSUES AND PREVENTION

Sunburn is a common skin condition that most people have experienced. Unfortunately, even one blistering sunburn before the age of 18 years will nearly double the lifetime risk of melanoma.[25,26] Having five or more blistering sunburns between ages 15 and 20 increases the risk of melanoma by 80% and the risk of nonmelanoma skin cancers by 68% in one study.[25,27] Thus, healthcare professionals who interact with the general public should promote the use of sunscreens and appropriate sun protection (eg, wide-brimmed hats, long-sleeve clothing) for everyone. In particular, patients on medications that can cause photosensitivity should be counseled to take sun precautions. Sun protection (ie, the use of sunscreens) should be year round—even on overcast days—as ultraviolet (UV) rays can penetrate the ozone layer, clouds, and windows.

UV radiation is associated with accelerated skin aging (photoaging) and skin cancers (eg, malignant melanoma, basal cell carcinoma). Skin should be constantly protected from UV damage by the use of sunscreens that block *both* UVA and UVB, with a sun protection factor (SPF) of 30 or higher. Sunscreens should be applied 20 minutes before sun exposure/heading outdoors and reapplied after sweating or swimming. UV rays can reflect off water and snow and some UV bands can penetrate through glass windows.

The UV spectrum is divided into three major bands with differing wavelengths: UVA (320-400 nm), UVB (290-320 nm), and UVC (270-290 nm). UVA is minimally filtered by the ozone layer, penetrates more deeply into the skin (dermis), and is responsible for most of the phototoxic reactions with drugs and chemical substances. Both UVA and UVB may cause photoaging, immunosuppression, and skin cancers. UVB is ~90% filtered by the ozone layer and, unlike UVA, does not penetrate through glass. However, UVB is the most active component for causing erythema (sunburn), with the greatest UV intensity between 10:00 am and 4:00 pm. A therapeutic benefit of UVB is the promotion of vitamin D synthesis in human skin. UVC is not of concern as it is 100% filtered out by the ozone layer.

Refer to Chapter e121, “Dermatologic Drug Reactions, Contact Dermatitis, and Common Skin Conditions” for further information on photoaging and skin cancers.

Risk Factors for Sun Damage

1. The UV index is a numeric system that rates the amount of UV rays reaching the earth's surface at any specific time at a specific location. The higher the UV index, the greater the exposure risk and hence sun damage. Factors affecting the UV index include: the time of day, the season, the altitude and latitude of the location, the integrity of the ozone layer, and whether there is land cover.
2. The amount of melanin present in a person's skin impacts susceptibility to sunburn over a given exposure period.
3. SPF is nonlinear—using an SPF 60 sunscreen does not mean one can stay out in the sun twice as long as using an SPF 30 sunscreen before burning.
4. The cumulative sun exposure over a person's lifetime is a risk factor for both photoaging and skin cancers.
5. Also mentioned earlier, one severe sunburn before age 18 doubles the lifetime risk of skin cancers (Table e17-2).

TABLE e17-2

Ultraviolet Index and Risk of Sunburn

Ultraviolet Index	Risk	Estimated Time for Person with Light Skin to Burn
0-2	Minimal	1 hour
3-4	Low Moderate	<20 minutes
5-6	High Extreme	<15 minutes
7-9	Low	<10 minutes
≥10	Extreme	<5 minutes

Data from Reference 28.

Sunburn

A sunburn is an acute dermatological reaction to excessive exposure to sunlight. As the UV rays penetrate the epidermis, an inflammatory reaction occurs, resulting in swelling of the endothelium and leakage of RBC from capillaries. The skin reddening peaks at 12 to 24 hours after sun exposure, then melanogenesis begins over the next 2 to 3 days, resulting in increased melanin in the epidermis and the appearance of a tan.

CLINICAL PRESENTATION

CLINICAL PRESENTATION: SUNBURN

Clinical presentation of sunburn may include erythema, skin tenderness/pain, itching, and/or edema. In more severe cases, there may be blisters, fever, chills, weakness, and shock. For 1 to 2 days after a sunburn, watch for signs of improvement/deterioration and refer to a physician if symptoms worsen or if there are signs of a secondary infection.

Prevention and Treatment of Sunburn

⑦ Due to the many negative effects and skin disorders relating to sun damage, sun protection at all times is critical, and this should be emphasized to patients, whether they are on medications with a photosensitivity potential or not.

Nonpharmacologic Means of Sun Protection

1. Limiting time in the sun, especially between 10 am and 4 pm
2. Wearing protective clothing
    a. Wide-brimmed hats
    b. Long pants
    c. Long-sleeved shirts (dark, loose-fitting, tightly woven)
    d. Sunglasses
    e. Sun protective clothing/UV absorbing agents

3. Avoiding tanning salons
4. Staying in the shade
5. Minimizing sun exposure if taking phototoxic or photoallergic medications

Sunscreens

Sunscreens “protect” against both sunburn and tanning, minimize UV-induced immunosuppression and skin aging, minimize the development of actinic keratosis while promoting the regression of existing lesions, and reduce the incidence of squamous cell carcinoma and malignant melanomas. Regular sunscreen use for the first 18 years of life could potentially decrease the lifetime risk of skin cancer by 80%—as mentioned earlier, one blistering sunburn before age 18 years almost doubles the lifetime risk of melanoma, and having five or more blistering sunburns between ages 15 and 20 years increased the risk of melanoma by 80% and nonmelanoma skin cancers by almost 70% in one study.[25–27]

There are two types of sunscreens: *organic* sunscreens act by absorbing UVA or UVB rays and thus blocking transmission to the epidermis; *inorganic* sunscreens act by reflecting and scattering UVA and UVB rays. Organic sunscreens are also known as chemical sunscreens and include substances such as para-aminobenzoic acid, or PABA, and/or other chemicals. Inorganic sunscreens—titanium dioxide or zinc oxide—are known as mineral sunscreens. These products used to be opaque (white on the skin), but many formulations now contain microfine particles that are transparent and cosmetically appealing. Products may be white upon application, but the color quickly disappears. This distinction is important. There is growing evidence fueling concerns that the chronic use of organic sunscreens may cause toxicity, since absorption occurs. The United States Food and Drug Administration (FDA) is assessing the risk and may issue new guidances.

In addition to the SPF (which should be 30 or higher as discussed), two other important characteristics to note when recommending a sunscreen are whether it is *broad spectrum* (ie, protects against UVA and UVB) and the *substantivity* of the sunscreen. Substantivity refers to the adherence of chemicals to the stratum corneum and determines the ability of a sunscreen to remain effective during prolonged exercising, sweating, or swimming. Substantivity may be a property of the active ingredients, the vehicle, or both. A water/sweat resistant sunscreen should retain efficacy for 40 minutes of water immersion and a water/sweat resistant sunscreen should retain efficacy for 80 minutes. (Remember to consider the time spent in the water as part of the total time spent in the sun.)

Patient-specific factors to note when recommending a sunscreen are the patient's skin type, level of physical activity, tanning history (if any), any known adverse reactions to sunscreen agents, and their preference (if any) for gels, creams, lotions, or sticks. Spray sunscreens carry a risk of inhalation and are not recommended, especially in children. The Canadian Dermatology Association (CDA) recommends that sunscreens should be noncomedogenic, hypoallergenic, nonirritating, and fragrance-free.

There is also a theoretical concern that sunscreen use may affect vitamin D production, since it is dependent on skin exposure to UVB. However, in practice, people may use inadequate sunscreen quantities, may not cover all sun-exposed skin, or may not reapply sunscreen regularly enough, so some vitamin D production still generally occurs.[27,29] The Institute of Medicine (IOM) recommended the same vitamin D intake irrespective of sunscreen use, setting the Recommended Dietary Allowance (RDA) for vitamin D based on minimal sun exposure[28] (ie, ensuring adequate vitamin D without the sun). This recommendation is followed in the United States[27] and Canada.[29]

SPECIAL PATIENT POPULATIONS

Sunscreen Use in Children

It cannot be emphasized enough the importance of sun protection to avoid even one sunburn in a child. As mentioned earlier, children who have a single blistering sunburn are twice as likely to develop skin cancer later in life, regardless of total exposure.[25,26] Always use an SPF 30 or greater broad-spectrum sunscreen and ensure that the most vulnerable areas (eg, nose, shoulders if not covered by clothing) are protected using an inorganic sunscreen.

The only exception to the routine use of sunscreens is in infants younger than 6 months of age.[30] As discussed earlier, neonatal skin (especially premature neonates) is less mature compared to adults, and neonates and infants have a higher BSA:BW ratio compared with older children and adults. For those reasons, exposure to chemicals in sunscreens may be much greater, increasing the risk of toxicity from the sunscreen.[30] Several nonpharmacologic alternatives are available for protecting babies from the sun. The best option is to avoid being in the sun at all—as much as possible, keep babies in the shade or shaded (eg, use a stroller cover). The American Academy of Pediatrics (AAP) suggests dressing infants in lightweight long pants, long-sleeved shirts, and brimmed hats that shade the neck to prevent sunburn—baseball caps are inadequate as they do not shade the neck and ears.[30]

The following are “sun safety tips for infants” younger than 6 months from the FDA.[31]

- Keep your baby in the shade as much as possible.
- Consult your pediatrician before using any sunscreen on your baby.
- Make sure your child wears clothing that covers and protects sensitive skin. Use common sense; if you hold the fabric against your hand and it is so sheer that you can see through it, it probably does not offer enough protection.
- Make sure your baby wears a hat that provides sufficient shade at all times.
- Watch your baby carefully to make sure he or she doesn’t show warning signs of sunburn or dehydration. These include fussiness, redness, and excessive crying.
- If your baby is becoming sunburned, get out of the sun right away and apply cold compresses to the affected areas.
- Hydrate! Give your child formula or breast milk if you’re out in the sun for more than a few minutes. Remember that infants are at much greater risk of overheating and dehydration. Store any liquid formula in a cooler per the product instructions.

Sun Protection During Pregnancy and Breastfeeding

Nonpharmacologic means is the management of first choice for women who are pregnant or breastfeeding. This includes sun avoidance in addition to protective clothing and shade. If using a sunscreen, both chemical and physical sunscreens are considered safe in pregnancy and lactation; however, care must be taken that an infant's skin does not come into contact with the treated mother's skin at any time (eg, while carrying or nursing the infant).[31]

CONCLUSION

Skin is vital for survival and must be cared for. Hydration—including appropriate skin moisturization and adequate oral fluid intake—is important for skin health. Appropriate sun care that avoids *all* blistering sunburns will reduce lifetime skin cancer risk—this needs to begin at birth. However, sunscreens should not be applied to babies younger than 6 months old because of potentially increased chemical toxicity—they should be protected by other means such as sun avoidance and shading. Suspicious moles/nevi should always be investigated to minimize the risk of melanoma—if in doubt, refer the patient.

SELF-ASSESSMENT QUESTIONS

1. Which of the following statements best describe the primary function of the epidermis?

   A. Provides support for skin structures such as sweat glands

   B. Allows blood vessels to pass through and reach the muscles

   C. Provides protection from the environment

   D. All of the above statements are correct.

2. The skin surface is normally covered with a hydrolipid film. Which of the following statements about the hydrolipid film is/are *correct*?

   A. It acts as a permeability barrier.

   B. It contains protein decomposition products.

   C. It contains transepidermal water.

   D. All of the above statements are correct.

3. Which of the following is *true* about the skin in an infant compared with adults?

   A. Infant skin is less predisposed to external insults than adult skin.

   B. Infant skin contains less moisture than adult skin.

   C. Infants absorb a greater proportion of topical drugs than adults.

   D. All of the above statements are correct.

4. Healthy skin is dependent on:

   A. Exercise

   B. Sleep

   C. Fluid intake

   D. Diet

   E. All of the above choices are correct

5. Bullae are also known as:

   A. Macules

   B. Papules

   C. Nodules

   D. Blisters

6. Application of sunscreens during childhood and adolescence is important for:

   A. Reducing the incidence of actinic keratosis but not lifetime risk of skin malignancies.

   B. Reducing the lifetime risk of skin malignancies but not incidence of actinic keratosis.

   C. Reducing the incidence of actinic keratosis and lifetime risk of skin malignancies.

   D. Reducing the incidence of neither actinic keratosis nor lifetime risk of skin malignancies.

7. Which of the following characterizes aged skin?

   A. Greater friability

   B. Prolonged healing time

   C. Less hydrated

   D. All of the above choices are correct.

8. Signs that a mole (nevus) may be dysplastic include:

   A. Size >5 mm

   B. Irregular shape

   C. Variable pigmentation

   D. All of the above choices are correct.

9. If skin hydration drops below 10%, all of the following may occur *except*:

   A. Skin cracks more easily

  B. Foreign elements penetrate more easily

  C. Skin cells mature more easily

  D. Mild inflammation

10. Essential fatty acid deficiency may manifest as:

  A. Dry scaly rash

  B. Impaired wound healing

  C. Hair loss

  D. All of the above choices are correct.

11. How do fragrance-free products differ from unscented products?

  A. They do not differ—the two terms are synonymous.

  B. Unscented products refer to personal toiletries such as talcum powder, whereas fragrance-free products refer to general household products such as candles.

  C. Fragrance-free products have the fragrance portion of the product removed, whereas unscented products do not contain synthetic chemicals.

  D. None of the above statements is correct.

12. Key points relating to percutaneous absorption include the following *except*:

  A. Absorption rate is faster if hair follicles are present in large numbers.

  B. Hydrophilic drugs and hydrophilic environmental toxins are absorbed faster than lipophilic substances.

  C. The stratum corneum can act as a “reservoir” for topical drugs and environmental toxins.

  D. The partition coefficient of a drug or environmental toxin is a useful predictor of percutaneous absorption.

13. The most common cause of an infected diaper rash is:

  A. *Candida* spp.

  B. *Staphylococcus aureus*

  C. *Streptococcus vaginalis*

  D. *Haemophilus influenzae*

14. Appropriate strategies for sun protection include all of the following *except*:

  A. Limiting time in the sun, especially between 10 am and 4 pm

  B. Wearing sun-protective clothing (such as wide-brimmed hats)

  C. Staying in the shade

  D. Using tanning salons rather than sun tanning

15. Appropriate management strategies for diaper dermatitis include all of the following *except*:

A. Air drying

B. Cleansing with a nonsoap cleanser and warm water

C. Using zinc oxide as a barrier cream

D. Using hydrocortisone 2.5% cream as prophylaxis

SELF-ASSESSMENT QUESTION-ANSWERS

1. **C.** As described in the introduction of this chapter, the four layers of the epidermis provide protection from the environment and perform a critical barrier function.

2. **D.** All of the listed statements are correct descriptions of the hydrolipid film. This is discussed further in the "Structure and Functions of the Skin" section.

3. **C.** As described in the "Age-Related Skin Differences" section, infant skin is thinner than that of adults, increasing the potential for drug toxicities secondary to increased topical absorption. Furthermore, the BSA:BW ratio in infants may be twice that of an adult's, resulting in higher systemic bioavailability for topical doses applied based on BSA. This is discussed further in the "Age- related and Ethnicity-Related Skin Differences" section.

4. **E.** As discussed in the "Skin Basics" section, skin health is related to overall health. Exercise and adequate sleep along with maintaining a healthy, well-balanced diet are key factors. Ample daily fluid intake and regular use of moisturizers are important for skin hydration.

5. **D.** As shown in Fig. e17-5, vesicles and bullae are the technical terms for blisters. Vesicles are circumscribed fluid-containing lesions of any size; bullae are vesicles with diameters larger than 0.5 cm.

6. **C.** Sunscreens "protect" against both sunburn and tanning, minimize UV-induced immunosuppression and skin aging, minimize the development of actinic keratosis while promoting the regression of existing lesions, and reduce the incidence of squamous cell carcinoma and malignant melanomas. Regular sunscreen use for the first 18 years of life could potentially decrease the lifetime risk of skin cancer by 80%—a single episode of blistering sunburn before age 18 almost doubles the lifetime risk of melanoma, and having five or more blistering sunburns between ages 15 and 20 years increased the risk of melanoma by 80% and nonmelanoma skin cancers by almost 70% in one study.

7. **D.** The "Age-Related Skin Differences" section describes characteristics of aged skin, including all of these factors. Aged skin tends to be drier, thinner, and more friable, which increases susceptibility to external insults and loss of the skin barrier function. In addition, the healing time after skin injury may be prolonged in aged skin.

8. **D.** These factors are all correct descriptors of a possibly dysplastic nevus, as described in the "Skin Assessment" section.

9. **C.** The "Skin Care Basics" section describes these effects of depleted hydration in skin: (1) the stratum corneum becomes brittle and may crack more easily; (2) mild inflammation and impaired cell maturation may occur; (3) foreign invaders may penetrate the skin more easily; and (4) chapping may result.

10. **D.** All of these sequelae can result from a deficiency of essential fatty acids, as described in the Nutrition subsection of this chapter.

11. **D.** A fragrance-free product does not contain synthetic chemicals, whereas an unscented product only has the fragrance portion of the product removed (ie, it may still contain synthetic chemicals, and these may be allergenic). Fragrance-free products are preferred to unscented ones. This topic is discussed in the "Scents and Fragrances" section.

12. **B.** Because the skin is made of lipids, absorption of lipophilic drugs and toxins occurs more rapidly than absorption of hydrophilic agents. Key points related to percutaneous absorption are discussed in the "Absorption Through the Skin"" section.

13. **A.** Diaper rash may be secondarily infected by *Candid*a species and present with confluent red plaques, papules, and pustules, as discussed in the "Diaper Dermatitis" section.

14. **D.** Both tanning salons and sun tanning should be avoided. Nonpharmacologic strategies for sun protection are discussed in the "Prevention of Sun-Induced Skin Disorders" section.

15. **D.** As discussed in the "Diaper Dermatitis" section, lower concentrations of hydrocortisone cream (0.5%-1%) can be used to treat diaper rash but only in severe cases and for limited periods of time (1-2 weeks).

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e

Chapter e18: Travel Health

Douglas Slain; Scott Kincaid

KEY CONCEPTS

KEY CONCEPTS

① Travelers should consult practitioners with travel health expertise when going to tropical or developing countries.

② For the pretravel consultation recommendations, travelers should be given written material in their language to reinforce and supplement verbal instructions.

③ The pretravel screening appointment should include a discussion of items that should be contained in a travel medical kit.

④ Pregnant travelers should consult obstetric and travel medicine experts prior to traveling to developing countries.

⑤ Immunocompromised patients may need longer periods of pretravel preparatory time to allow for adequate immunization, given their sometimes blunted antibody responses to vaccines.

⑥ Travelers to sub-Saharan Africa, Southern Asia, Central and South America, and the Caribbean experience higher rates of infection than those traveling to other parts of the world.

⑦ Prophylactic antibiotic use may reduce the risk of traveler’s diarrhea but is generally not recommended, primarily because of the risk of developing drug resistance or *Clostridioides difficile* infection.

⑧ Prevention strategies are essential for limiting vector-borne infections during travel.

⑨ The mainstay of therapy in all altitude-related illnesses is descent to a lower altitude (typically at least a 300-m reduction in altitude).

⑩ Patients who have previously been diagnosed with depression should continue their prescribed medications and minimize alcohol consumption while traveling.

BEYOND THE BOOK

BEYOND THE BOOK

Design a medication kit for a family of four (two adults and two preteen children) taking a 10-day trip to Aruba.

INTRODUCTION

Global (international) travel has increased dramatically over the past 20 years. A sizable proportion of this increased travel can be explained by individuals traveling from developed countries to developing countries.[1] Reasons for travel to developing countries are variable, but include work-related travel, leisure travel, medical tourism, visiting family, adventure travel, medical mission or outreach, and study abroad programs.

Travel to distant lands has always been associated with risks to mental and physical health. Long-standing estimates of travelers experiencing health problems have been between 22% and 64%, and more recent data tell us that travelers visiting developing and/or tropical nations may experience illness 43% to 79% of the time.[2] Many health problems arising during travel are self-limiting or not bothersome enough for travelers to seek medical care. However, approximately 8% of travelers seek help from physicians either during or soon after traveling.[3] In addition to infectious and noninfectious health problems, global travelers face potential dangers from vehicle and pedestrian traffic accidents, drowning, animal attacks, and assaults. This chapter focuses on health risks and diseases that affect global travelers, with primary emphasis on travel from developed countries to developing or tropical countries. Some travel-related information is included in other chapters, and readers will be referred accordingly.

PRETRAVEL PREPARATION

① Travelers should review information about their destinations and itinerary and consider potential self-care options for health issues that may arise during travel. Pretravel preparation often involves the assistance of healthcare providers, which is typically more important for patients with chronic health conditions and those traveling internationally, especially to the developing world. About 35% to 50% of travelers from North America and Europe heading to developing countries seek pretravel health advice.[4] Of whom, only about 10% to 20% of travelers consult travel medicine experts or travel clinics. Informed primary care providers without extensive travel health expertise can provide adequate advice to travelers en route to low-risk destinations, but travelers should consult practitioners with travel health expertise when going to tropical or developing countries.[4]

Travel clinics and travel health experts are often underutilized.[4] Two groups of travelers that are less likely to seek expert pretravel health advise are business travelers and immigrants living in developed countries, going back to their home countries to visit friends and relatives (VFR).[5,6] VFR individuals often believe that they are immune to local diseases and do not feel the need to seek advice.[6] Unfortunately, VFR travelers often display some of the highest rates of travel health problems.[4,6] US residents traveling on global VFR trips make up about 33% of all travelers.[7] Other travelers may not seek travel expert advice for travel to resorts in nearby countries. However, even travelers staying at all-inclusive Caribbean resorts are subject to travel health issues.[8]

Practitioners seeking to become travel medicine experts can gain expertise and credentials in travel health through many different pathways. The majority of travel medicine specialists are primary care and infectious diseases physicians, but other types of physicians, pharmacists, nurse practitioners, nurses, and physician assistants can also become travel health specialists. Many US specialists complete certification programs offered by either the International Society of Travel Medicine (ISTM) or the American Society of Tropical Medicine and Hygiene (ASTMH).[4] In addition, some travel experts have specific expertise in the diagnosis and treatment of illnesses acquired in the tropics (tropical medicine). Travel health consultants with extensive travel experience can be helpful to travelers, especially if they have traveled to the same region that the traveler intends.

The Pretravel Consultation

② Global travelers should make pretravel consultation appointments several weeks to months before traveling to allow time for adequate immunizations.[1] "Last-minute travelers" can create a unique challenge for pretravel advisors, who may have to devise less than optimal preparations.[9] The pretravel consultation should be performed in a structured and standardized manner (Table e18-1).[1,3,4,10] There should be an assessment of the traveler's health and pertinent medical history, including a thorough medical history, travel history, medications, vaccinations, and allergies. Next there should be an assessment of the traveler's risk, including discussion about the destinations, itinerary, accommodations, and planned activities. The consultant should have access to up-to-date travel health references on the travel destination and should provide preventative advice. Principal discussion points (depending on destination) may include vaccine-preventable illness, avoidance of insects, malaria prophylaxis (if applicable), prevention and self-treatment of traveler's diarrhea (including food and drink safety), responsible personal behavior (ie, discussions about alcohol and substance use), sexually transmitted infections (STIs), general safety, travel medical insurance, and access to medical care during travel.[4,11] Pretravel screening also provides an excellent opportunity to assess travelers' routine immunization status. For individuals in the United States, a review of the Centers for Disease Control and Prevention (CDC) Advisory Committee on Immunization Practices (ACIP) recommendations will help to identify routine vaccinations that should be offered to travelers for their general health based on age, vaccination history, comorbidities, and planned travel.[10] Travelers should receive any recommended vaccines in time to provide protection prior to travel. Refer to Chapter 147, “Vaccines, Toxoids, and Other Immunobiologics” for a discussion of routine vaccinations. Finally, the consultant should provide posttravel advice, if relevant. This typically involves reminders about continuing malaria prophylaxis (if appropriate) and a discussion about self-assessment of any abnormal symptoms. During the pretravel consultation, travelers should be given written material in their language to reinforce and supplement verbal instructions. Written material can also include citations for online or printed resources.[4,10]

TABLE e18-1

Template of a Structured Pretravel Consultation

Stage	Elements
Risk assessment	• Assess current state of health • Complete a thorough medical history (including medication and allergy history) • Review travel itinerary (including countries visited, routes of transportation, season, and accommodations) • Discuss planned and possible activities in which the traveler might participate
Preventive advice	• Recommend routine vaccinations if not up to date • Recommend destination-specific travel-related vaccinations • Discuss prevention of vector-borne illness including need for malaria prophylaxis (if applicable) • Provide food and drink safety tips and traveler’s diarrhea counseling • Review noninfectious travel conditions (motion sickness, jet lag, altitude sickness, and travel-associated venous thromboembolism) • Discuss travel medical kits
Immunizations and prescriptions	• Provide any needed recommended vaccinations • Prescribe/dispense antimalarial prophylaxis medications, motion sickness medication, and empiric medications for traveler’s diarrhea
General safety and health advice	• Discuss travel health resources • Discuss personal safety and sexual health • Discuss alcohol and drug use • Comment on travel insurance and medical evacuation coverage • Provide posttravel advice • Provide written material to the traveler to reinforce and supplement verbal instructions discussed during appointment

Data from References 1,3,4,10.

Travel Medical Kits

Assembling a medical kit is an essential part of preparing for any international travel.[12,13] The kit can contain medications and health-related supplies for a single traveler, a family, or a group of travelers and can vary from a few nonprescription medications to several large containers of medications and health-related supplies for a group. Some common kit items are nonprescription medications, sunscreen, chronic prescription medications, antimalarial agents, anti-infectives for traveler’s diarrhea, motion sickness medications, first aid kit items, sanitizing hand gel or wipes, insect repellant, potable water tablets, topical antibacterial ointments, rehydrating salts, and surgical masks. Table e18-2 contains a list of items that travelers could consider taking in their medical kits.

TABLE e18-2

Potential Items for Personal Travel Medicine Kits[a]

Type of Medical Kit	Items
Basic items	• Personal prescription medications as permitted by the host country • Nonprescription analgesics • Nonprescription antidiarrheals • Antihistamines • Decongestants • Laxative • Antacid • Sunscreen • Lip balm • Insect repellant • Alcohol-based hand gel • Motion sickness medications • Antimalarial prophylaxis (if needed) • Antibiotics for empiric treatment of traveler's diarrhea • Antiseptic wipes • Water purification tablets (if needed) • Basic first aid items (bandages, antibiotic ointment, tweezers) • Topical corticosteroid cream • Antibiotic cream • Tissues • Digital thermometer • Melatonin (for jet lag)
• Comprehensive personal items • *Consider for high-risk travelers like backpackers on longer independent trips to developing countries*	• Medical exam gloves • First aid dressings • Medical tape • Healing plasters • Wound closures • Blister plasters • Support bandage • Artificial tears • Eye wash • Antibiotic eye and ear drops • Topical antifungal medication • Antiemetic • Medications for altitude sickness • Temporary dental fillings • Empiric malaria treatment • Epinephrine auto-injector
Additional items for special circumstances	• Antiretroviral agents for postexposure prophylaxis (if providing direct care to HIV-infected patients)

	- Doxycycline for leptospirosis prophylaxis (consult a travel medicine specialist for need) - Condoms

[a]Table has been developed for travel to developing countries.

Data from References 12,13.

3 The pretravel screening appointment should include a discussion of items that should be contained in a travel medical kit based on a thorough risk assessment that considers traveler health history, destinations, duration, and type of activities. Travelers also need to anticipate available medical resources while traveling. Unfortunately, counterfeit or poor-quality medications can be found in the shops and hospitals of many countries.[1] Therefore, travelers should bring important medications from home. Limited access to hospitals, doctors, and pharmacies may require the traveler to carry many items in their medical kits. Small groups can order commercially prepared medical/first aid kits from travel specialty supply companies and web-based mass marketers (eg, Amazon.com) that can serve some of the general needs of the group while individual members assemble personal kits for individualized needs.[12] In general, most medications in kits should be suitable for self-administration. Preparation of medical kits for larger travel groups can be much more extensive and may need to be maintained by a healthcare provider.[12]

Travelers may have their medications examined by security or customs officials when entering certain countries.[12,14] To facilitate travel with medications (nonprescription or prescription), it is best to avoid having opened containers with loose tablets and capsules when possible. As a general rule, individually packaged and labeled medications ("units of use") or sealed commercial bottles will raise less scrutiny and may better protect medications. In addition, waterproof packaging may be needed for certain travel destinations or wilderness travel. Traveling with controlled substances or psychotropic medications can create additional difficulties.[12] Travelers with controlled or psychotropic medications should check the International Narcotics Control Board (INCB) website (www.incb.org) or official governmental sites of the destination country before traveling with such substances.[12,14] Countries may not permit the entry of some substances by travelers, or there may be criteria for entering with certain medications.

Travelers with Special Concerns

Older Adults and Travelers with Chronic Conditions

Older travelers with chronic conditions or those who lack strength and agility should be evaluated by their physician for fitness to travel. Some destinations and activities require more strength and stamina than others. Accidental traumas are a leading cause of death among older travelers, in part because of slow reaction time, poor coordination, and auditory or visual impairment.[15] The most common natural causes of death among older travelers are cardiac related. The stress of travel, poor oral intake, dehydration, physical exertion, and medication nonadherence may contribute to these deaths.[15]

Travelers of any age with chronic health issues must self-monitor their conditions and take medications appropriately. More patients with chronic conditions are traveling now due largely to advances in medicine.[16] Eighteen percent of travelers to developing countries have a chronic illness.[17] Travelers with chronic conditions should check with their physicians as they plan to make global travel plans.

Pregnant Travelers

4 The frequency of pregnant females traveling to developing countries is considerably higher among VFR travelers than non-VFR travelers.[6,18] Pregnant travelers should consult obstetric and travel medicine experts prior to traveling to developing countries.[1] Pregnancy presents added challenges for travelers heading to developing countries. For example, live vaccines are contraindicated during pregnancy. The concern with live vaccines is that they can transmit vaccine strain illness to the fetus.[18] Some live vaccines may need to be used if the benefit is believed to outweigh the risk to the fetus. With regard to antimalarials, chloroquine has been the antimalarial agent of choice in pregnancy.[18] Mefloquine, which has not been extensively studied in pregnancy, is believed to be safe and has been supported as a first-line agent.[1,19,20] Antimalarial decisions can be difficult if

traveling to chloroquine- and mefloquine-resistant regions because the safety of alternatives is less certain. Atovaquone-proguanil has not been well studied in pregnancy and carries Food and Drug Administration (FDA) category C pregnancy rating.[18] Doxycycline is contraindicated because of detrimental effects on bone and teeth development.[18] All females of childbearing age should know their pregnancy status before receiving live vaccines or malaria prophylaxis.

Pregnancy places long-distance travelers at high risk for venous thromboembolism (VTE) especially during air travel.[21] Unfortunately, VTE prevention data in pregnancy are limited. The American College of Chest Physicians (ACCP) lists two recommendations for pregnant persons making long-distance travel in the Antithrombotic Therapy and Prevention of Thrombosis guidelines[22]: (1) frequent ambulation, calf muscle exercise, or sitting in an aisle seat if feasible, and (2) use of properly fitted, below-knee graduated compression stockings providing 15 to 30 mm Hg (2-4 kPa) of pressure at the ankle during travel. These actions were given a grade of 2C, which is defined as a weak recommendation from low-quality studies. These approaches are not likely to harm, and so they are frequently advised.[1,21]

The first and third trimesters of pregnancy have been the most worrisome for global travelers. Fetal development complications and miscarriages are most common during the first trimester.[18] Preventive vaccines and medications should be used with caution during this time. During the third trimester, women are generally uncomfortable and at risk of preterm labor. Airlines and cruise ships may require documentation for pregnant travelers at or beyond 36 weeks of gestation.[18] Cabin pressurization on commercial airlines is not expected to be a problem for uncomplicated pregnancies, but any influence on more complex pregnancies has not been well assessed.[23] Women who plan to travel during the third trimester should assess available medical facilities at the destination in anticipation of potential complications or early delivery. Health insurance companies should also be contacted prior to travel to confirm any coverage restrictions.[18]

Immunocompromised Travelers[26,27]

Travelers with compromised immune systems may face increased risk of infection during travel; however, this does not usually prevent them from traveling. Twenty-seven percent of US solid-organ transplant recipients reported travel outside North America and 20% to 46% of people living with human immunodeficiency virus (HIV) infection travel internationally.[24] Patients prescribed biologic agents to manage chronic inflammatory conditions may be at an increased risk of developing infections if traveling to areas with endemic fungi and tuberculosis.[25] Many immunocompromised patients are at an increased risk of traveler's diarrhea, largely because of impaired mucosal immunity.[26] Immunocompromised patients should involve travel experts and their specialist physicians in pretravel assessment.[1]

⑤ Immunocompromised patients may need longer periods of pretravel preparatory time to allow for proper vaccination, given their sometimes blunted antibody responses to vaccines. Additional time to assess serologic titers with possible booster immunization may be required.[26] Live vaccines are contraindicated in many immunocompromised patients, because the vaccine strain may cause an active infection. For patients with HIV infection who need vaccines for travel, immune responses are thought to be better and the chance of vaccine infectivity is reduced when the CD4+ cell count is 200 cells/mm^3 (0.2 × 10^9/L) or greater.[26,27] Counts of 500 cells/mm^3 (0.5 × 10^9/L) or greater are preferred for immunization, if possible. Live vaccine use has also been associated with organ rejection in solid organ transplant recipients.[26]

TRAVEL-RELATED DISEASES

Infectious Diseases

Infection and global travel have been linked throughout history. Up to 10% of global travelers develop infections during travel.[3] However, many of these infections could be avoided through proper vaccination and risk avoidance. Travelers themselves have served as conduits for spreading various infectious diseases across the globe. For example, travelers from China brought cases of the severe acute respiratory syndrome (SARS) to North America in 2003 and SARS-CoV-2 in 2019.[28]

⑥ Travelers to sub-Saharan Africa, Southern Asia, Central and South America, and the Caribbean experience higher rates of infection than those traveling to other parts of the world.[29] The major routes of infection in the developing world include (1) food or waterborne pathogens spread via fecal-oral transmission, (2) insect vector-borne infections, (3) transcutaneous spread (eg, helminthic), (4) respiratory -spread, and (5) STIs.

Food- and Waterborne Infections

Diarrheal Illness. Gastrointestinal ailments are common among travelers.[1] Nausea, gas, and changes in stool consistency and frequency can occur in even the most cautious global travelers. These changes can be brought on by changes in diet, stress, and alteration of gastrointestinal flora.[2] Most diarrheal and gastroenteritis episodes are caused by the consumption of infectious (fecal) contaminated food or water.[4] The entity called *traveler's diarrhea* is defined as three or more unformed stools per 24 hours plus at least one additional symptom (abdominal cramping, tenesmus, nausea, vomiting, fever, or fecal urgency).[30] Traveler's diarrhea, which can be caused by bacteria, viruses, and protozoa, has an incidence of 25% for 2-week global travels.[31] The highest rates of infection occur in Asia, the Middle East, Africa, and Central America.[30,31] See Chapter 136, "Gastrointestinal Infections and Enterotoxigenic Poisonings" for additional discussion of traveler's diarrhea.

Common bacterial causes of traveler's diarrhea include: enterotoxigenic or enteroaggregative strains of *Escherichia coli*, *Campylobacter*, *Salmonella* (nontyphoidal), and *Shigella*. Common viral causes include: Rotavirus and Norovirus.[1,31,32] The most common protozoal cause of traveler's diarrhea is *Giardia species*. Less common protozoal causes include: amebiasis (*Entamoeba histolytica*), Cryptosporidiosis, and Cyclosporiasis. With the exception of Cyclosporiasis, protozoal disease onset usually takes longer because of a 1- to 2-week incubation period.[1] Infections caused by these organisms and their treatment are discussed in Chapter 136. Some humanitarian workers may also travel to areas with cholera (*Vibrio cholerae*) epidemics. These are typically in poor regions of sub-Saharan Africa, parts of southern Asia, and Hispaniola.

A key feature of the pretravel consultation should include a discussion about safe eating and drinking practices. Risk avoidance is the best way to reduce the occurrence of traveler's diarrhea, but it is difficult to avoid all risks. Even following the old adage "boil it, cook it, peel it, or forget it" may not always protect travelers.[31,32] Exposure to contaminated water during recreation or drinking (including ice cubes) remains a common cause of infection.[33,34] Several water purification techniques and products are available. They include heat, filtration, ultraviolet light treatment, halogen treatment, and chlorine dioxide-based treatment.[33] Convenient personal filter straw devices are easy to pack and carry. Each method has advantages and disadvantages that can be discussed with travel health experts. Heat is generally the most consistent method, but it has difficulty in masking bad tastes and odors.

Oral bismuth subsalicylate has been used to prevent traveler's diarrhea.[32,36] Daily use of bismuth subsalicylate was 65% effective in preventing traveler's diarrhea during a 3-week clinical trial in Mexico.[32] Common side effects include darkening of the tongue and stool. The drug is contraindicated in patients who should not take salicylates (ie, hypersensitivity to salicylates, children). Bismuth subsalicylate also interferes with the absorption of doxycycline, which is often used in travel medicine.[4,32] Probiotics are believed by some to reduce the occurrence of infection, but supportive data have not been consistent.[32]

⑦ Although prophylactic antibiotic use can reduce the risk of traveler's diarrhea, such use is generally not recommended, primarily because of the risk of developing drug resistance or *Clostridioides difficile* infection.[1] Travelers can bring antibiotics in their medical kit for self-directed initiation for symptomatic disease along with antimotility agents like loperamide.[12,13] The recommended adult empiric antibiotic regimen is single-dose or short-course oral fluoroquinolones (eg, ciprofloxacin 500 mg daily for 1-3 days) or azithromycin (500 mg daily for 3 days or 1,000 mg once).[32] Azithromycin may now be preferred in South or Southeastern Asia because of the increased presence of fluoroquinolone-resistant *Campylobacter*. A minimally absorbed delayed-release rifamycin tablet is approved for the treatment of travelers' diarrhea caused by noninvasive strains of *E. coli* in adults.[32] Dehydration is a serious side effect of pronounced diarrheal illness, despite antibiotics. Travelers to remote areas with high rates of traveler's diarrhea should consider packing oral rehydration solution powder.[4,31]

Good hand hygiene is also important for limiting traveler's diarrhea. Unfortunately, travelers may not always have access to soap and clean running water. This can be a concern for travelers in remote areas without water and "squat potty" restrooms. Alcohol hand sanitizers reduce the occurrence of traveler's diarrhea and thus should be used when soap and water are not available.[34]

Vaccine-Preventable Food- and Waterborne Pathogens. Typhoid fever (caused by *Salmonella enterica* serotype Typhi) is a serious disease spread by contaminated food and water. Clinical presentation may include high fever, weakness, stomach pain, headache, loss of appetite, constipation, and rash. Internal bleeding and death can occur rarely.[1] The ACIP recommends typhoid vaccine for travelers to certain countries (see https://wwwnc.cdc.gov/travel). Vaccination may be given by either injectable killed Vi capsular polysaccharide vaccine or by oral live-attenuated Ty21a vaccine.[1,35] The injectable vaccine is recommended as a single IM injection for travelers older than or equal to 2 years. A booster is recommended if needed for travel every 2 years.[35] Immunization with the live oral capsule vaccine consists of one capsule taken every other day for four doses. A booster can be taken every 5 years if needed. The live vaccine is for travelers older than or equal to 6 years. The capsules must be refrigerated and taken with cool water. The oral vaccine has been associated with more gastrointestinal side effects and rash. The live vaccine is contraindicated in immunocompromised travelers, and pregnancy is an additional caution.[1,35]

For travelers going to cholera epidemic areas, there is an oral live-attenuated vaccine available.[1] Cholera vaccines may provide some protection against some strains of enterotoxigenic *E. coli*.[3] Hepatitis A is a picornavirus shed in the feces of infected persons that can contaminate food and water. Vaccination is now widely available in the United States and other developed nations and has become a standard pediatric vaccine (see Chapter 58, “Viral Hepatitis”).[36]

Vector-Borne Infections

⑧ Infections transmitted by arthropods (eg, insects) are common in the developing world. Vector-borne infections can range from asymptomatic to fatal. Figure e18-1 displays a WHO world map of the overlapping global distribution of nine major vector-borne diseases. The map highlights regions of the world where malaria, lymphatic filariasis, dengue, leishmaniasis, Japanese encephalitis, yellow fever, Chagas disease, human African trypanosomiasis, and onchocerciasis are endemic. The majority of vector-borne infections are attributed to arboviruses, which is a term that means arthropod-borne virus.[37] These include dengue fever, chikungunya, yellow fever, Japanese encephalitis, and Zika. Most of these infections do not have reliable treatments.[38] Therefore, prevention strategies are essential for limiting vector-borne infections. Such “risk avoidance” strategies should include avoiding infected habitats, wearing protective clothing, using protective bed netting, and applying insect repellent.[39] If available, the use of recommended vaccines would also be essential. Travelers with flexible travel plans can reduce exposure by traveling during seasons with less insect activity (ie, the dry season). Travelers should also be educated about daily insect activity patterns. While insect bites can occur at any time of day or night, there are times of increased insect activity. For example, mosquitoes that transmit dengue, yellow fever, and chikungunya bite more frequently between dawn and dusk, whereas mosquitoes that transmit malaria and Japanese encephalitis primarily bite from dusk to dawn.[1] Exposure to mosquitoes and other insects may occur indoors as well as outdoors. Exposure risk is reduced in air-conditioned buildings or in areas that do not have direct exposure to the outdoors.[38] The use of pyrethroid insecticide-treated bed netting provides a greater protective effect than untreated netting.[38]

Wearing protective clothing that limits access to human skin in areas of high insect activity is highly advisable. This can be a challenge in very hot climates or when participating in outdoor activities. Application of EPA-registered insect repellants such as DEET (*N*,*N*-diethyl-3-methylbenzamide) or picaridin to the skin can provide protection against vector-borne disease. Unfortunately, compliance with daily application can be suboptimal.[40] For best effect and safety, DEET 20% to 50% concentration should be used.[1] Travelers should be provided with written material about proper application to reduce the risk of repellant toxicity. In addition, it is advisable to purchase repellants in developed countries to ensure product quality. Clothing can also be sprayed with repellants to increase protection.[40] This is often done before packing the clothes in luggage. Alternatively, clothing pretreated with repellants and insecticide agents like permethrin can be purchased through specialty travel vendors.

When infected with arboviruses, humans experiencing periods of high viremia can serve as amplification sources of infection if they remain in areas with mosquito activity. These individuals should continue to be protected from mosquitoes to reduce the further spread of infection.

Mosquito-Borne Infections. Malaria, which is caused by *plasmodium* protozoa and spread by *Anopheles* mosquitoes, is an important travel-related infection. Travelers to malaria-affected regions should discuss preventative strategies with an expert during pretravel consultation. The selection of prophylactic medications (if any) is based on potential efficacy, safety, and affordability. Antimalarial drugs should always be purchased before traveling overseas. In the developing world, antimalarial drugs can be purchased, but they may be counterfeit, subject to resistance, or of substandard quality.[1] Malaria is discussed in more detail in Chapter e138, "Parasitic Diseases."

Dengue fever is caused by one of four related single-stranded RNA *Flaviviruses*, named dengue virus (DENV) 1, 2, 3, or 4.[41] DENVs are endemic in over 100 countries throughout the tropics and subtropics, which includes parts of the Americas, the Caribbean, Africa, South Asia, and Oceania. Areas of recent dengue fever activity can be seen on the Healthmap.org surveillance website (https://www.healthmap.org/dengue/en/index.php). Dengue is the most common vector-borne infection affecting travelers in tropical and subtropical countries, with 100 million dengue cases per year and 10,000 deaths annually.[42] Dengue cases have surpassed malaria in all regions except for sub-Saharan Africa, but that may change.[43] Dengue is also more common in urban and suburban environments than malaria because of the type of mosquito vector.[41] DENV transmission is facilitated by the daytime-biting *Aedes aegypti* or *Aedes albopictus* mosquitoes.

Most patients with dengue fever experience either an asymptomatic (up to 80%) or a self-limiting, febrile illness that can be quite pronounced.[1,44] Classic symptoms include acute onset of high fever, severe headache, retro-orbital pain, fatigue, myalgia, arthralgias, and rash.[44] As its former name "break-bone fever" suggests, bone and joint pain can be quite intense. About 5% of infected individuals go on to develop severe infection with shock, which typically involves plasma leakage (increased vascular permeability) with or without bleeding.[42,44] Severe infections may include hepatitis, neurologic disorders, myocarditis, blood dyscrasias, shock, or severe bleeding.

The clinical course of dengue in symptomatic cases occurs in three stages: (1) febrile stage, (2) critical stage, and (3) recovery. During the first stage, fever lasts from 2 to 7 days. Patients experience defervescence as they enter the critical phase, which is characterized by some degree of plasma leakage. Most patients improve during this phase, but others progress to more severe diseases. As plasma leakage diminishes, the patient enters the recovery phase. After any DENV infection, patients usually have lifelong protection against that specific DENV serotype. Unfortunately, patients subsequently infected with a different serotype may develop an extremely severe secondary infection that is triggered by an immune response in the presence of cross-reactive nonneutralizing antibodies.[41,44,46,49,50]

Classic dengue fever is rarely fatal among travelers, but they may require hospitalization and even medical evacuation to their home countries for care. Mortality rates may be up to 20% in severe infection if left untreated, whereas patients receiving proper supportive care have only a 1% mortality rate.[41] Acetaminophen is preferred over aspirin or other nonsteroidal anti-inflammatory drugs (NSAIDs) for fever reduction because of the increased risk of bleeding with symptomatic disease.[44,49] There are no established antiviral medications to prevent or treat dengue fever. However, a new quadrivalent vaccine has been approved in several countries for children with laboratory-confirmed previous dengue infection and living in endemic areas.[45] The vaccine is not being used for primary prevention because of severe subsequent infections in children who received the vaccine. Risk avoidance remains the best way to prevent dengue.[46]

The Zika virus is a related RNA flavivirus, which is also spread by the Aedes mosquitoes and became more widespread around 2015 when it appeared in Latin America.[47] Since that time, it remains endemic across parts of Central and South America.[48] Zika infection is usually asymptomatic, but can present with similar, but often milder symptoms than Dengue. Unfortunately, Zika infections in pregnant patients have been associated with microcephalic babies.[47] There is added concern for this birth defect given that the virus can also be transmitted sexually from infected males to uninfected females. The CDC has posted advice for individuals who have traveled to endemic regions and may be at risk for spreading Zika sexually (https://www.cdc.gov/zika/pdfs/fs-zika-sex-partnertravel.pdf). No antivirals are available for Zika, but a vaccine is currently in development.[49]

Chikungunya virus (CHIKV) is a single-stranded RNA *Togavirus*. CHIKV transmission is facilitated by the daytime-biting *A. aegypti* or *A. albopictus* mosquitoes. CHIKV was initially endemic in rural parts of Africa but spread to Indian Ocean nations, Asia, and the Americas over the past 70 years.[50] Prior to 2013, CHIKV was not active in the western hemisphere.[51] Since that time, the virus has become endemic in Central America and South America and the Caribbean. The number of suspected or confirmed cases of CHIKV has now reached 2.9 million in the Americas.[52] Worldwide estimates of CHIKV activity are difficult to tabulate, but CHIKV is most endemic in South America, Central America, and parts of Southern Asia at this point.[48]

About 3% to 28% of people infected with CHIKV remain asymptomatic.[1] After an incubation period of about 3 to 7 days, symptomatic patients may abruptly manifest symptoms of high fever, headache, back pain, myalgia, and intense arthralgias.[53] A variety of skin manifestations also accompanies infection in 40% to 50% of infected persons, with maculopapular rash predominating. Given similar symptoms, the same vector, and overlapping endemic regions, it can be difficult to distinguish chikungunya from dengue. Incapacitating arthralgias (primarily of the hands and feet) are said to occur more with chikungunya.[53] Dengue patients experience more blood dyscrasias. There are no FDA-approved vaccines, but at least one in development.[54] Risk avoidance is the best way to avoid chikungunya infection. Supportive care and treatment is similar between chikungunya and dengue, except that NSAIDs can be used in the care of CHIKV-infected patients because of the lack of thrombocytopenia or hemorrhagic complications in this condition. CHIKV infection is rarely fatal (<1%), although the elderly may have worse prognoses than younger individuals.[51]

Japanese encephalitis virus (JEV) is a single-stranded RNA *flavivirus* that is transmitted to humans by the *Culex* species mosquitoes. Pigs serve as a major reservoir for the virus, but wading birds can also serve as reservoirs.[55] Endemic regions for JEV include East Asia, western Asia islands between the main continent and the northern tip of Australia, and the Indian subcontinent. The transmission risk is much lower than with dengue or malaria, with an estimated incidence of less than 1 case per 1 million travelers.[56] Rates are much higher if travelers stay longer in endemic areas or have significant rural exposure (ie, near pigs and rice paddies). In the more temperate regions of northeast Asia, JEV transmission is seasonal; epidemics are more likely to occur between April and October.[57] In the subtropics and tropics, transmission can occur year round but may intensify during the rainy season.

Most humans develop asymptomatic JEV infection; less than 1% of infected patients develop symptoms.[1] The most common manifestations include fever, flu-like symptoms, acute encephalitis, or aseptic meningitis. Humans infected with JEV do not experience very high viremia and are therefore less likely to amplify the spread of infection.[55,56] JEV has been associated with severe illness and a case-fatality rate of 20% to 30% with neurologic sequelae in 30% to 50% of severe infection survivors.[56] Fortunately, vaccines are available to prevent infection. The vaccine available in North America and Europe is an inactivated JEV SA14-14-2 strain prepared in Vero cells (trade name: Ixiaro). It is administered in a two-dose series given 28 days apart.[58] The vaccine contains protamine sulfate, which may be associated with hypersensitivity reactions. Very rare but serious reactions including anaphylaxis could occur following vaccination.[4,58,59]

The JEV vaccine is recommended for travelers who plan to spend a month or longer in endemic areas during the JEV transmission season (season varies with latitude).[56] This includes long-term travelers or expatriates who will be based in urban areas but are likely to visit endemic rural or agricultural areas during a high-risk period of JEV transmission. The JEV vaccine should be considered for short-term (<1 month) travelers to endemic areas during the JEV transmission season if they plan to travel outside of an urban area and have an increased risk for JEV exposure (eg, spending substantial time outdoors in rural or agricultural areas; participating in extensive outdoor activities; staying in accommodations without air conditioning, screens, or bed nets), and travelers to an area with an ongoing JEV outbreak or travelers to endemic areas who are uncertain of specific destinations, activities, or duration of travel. JEV vaccine is not recommended for short-term travelers whose visit will be restricted to urban areas or periods outside of a well-defined JEV transmission season. The vaccine is FDA approved for adults and children as young as 2 months of age.[58]

Yellow fever (YF) virus is a single-stranded RNA *flavivirus* that is spread by *Aedes* or *Haemagogus* species of mosquitoes. The WHO estimates that 200,000 cases of YF and 30,000 deaths attributable to YF occur annually.[60] The major areas of endemic YF activity are equatorial South America and sub-Saharan Africa (within 15 degree of the equator). YF virus has three transmission cycles: jungle (sylvatic), intermediate (savannah), and urban, each with different proportionate roles for nonhuman and human primates as a source of vector-facilitated transmission.[60]

Yellow fever infections cause asymptomatic or subclinical infections in the majority of infected persons.[1] Symptomatic individuals can experience variable clinical presentations that can range from mild, undifferentiated febrile illness to severe disease with jaundice and hemorrhagic manifestations. Infected patients can experience an abrupt onset of a high fever (up to 104°F [40°C]), chills, severe headache, myalgia, back pain, anorexia, nausea, prostration, vomiting, and dizziness. Some infected patients develop a severe form of illness characterized by jaundice, hemorrhagic symptoms, shock, and multiorgan system failure, after a brief (hours to days) remission period.[1] Case-fatality rates are 20% to 50% in severe cases.[61]

While there are no effective antiviral medications to treat YF, vaccines can prevent infection. At least four live-attenuated vaccines are approved by the WHO.[1] The formulation available in North America is a 17D-204 strain (trade name: YF-Vax).[62] The vaccine is recommended as a single-dose immunization for adults and children at least 9 months of age. Immunity usually develops by the 10th postvaccination day. Reimmunization was recommended every 10 years for those at continuing risk of exposure, but most experts do not recommend a “booster” dose because the vaccine provides immune protection for many decades.[1,60]

Adverse reactions to the YF vaccine include local site reactions, mild headaches, myalgia, and low-grade fevers, which can last for 5 to 10 days.[62] The product labeling carries precautionary warning about three serious adverse reactions. The first is immediate hypersensitivity reactions including anaphylaxis, mainly seen in patients with egg allergies. The vaccine is contraindicated in anyone with a history of acute hypersensitivity reaction to any components of the vaccine (including gelatin) or a history of acute hypersensitivity to eggs or egg products. The second serious reaction is vaccine-associated neurotropic disease (referred to as YEL-AND), previously described as postvaccination encephalitis. YEL-AND also includes acute disseminated encephalomyelitis, Guillain-Barré syndrome, bulbar palsy, and Bell’s palsy.[40] Finally, vaccine-associated viscerotropic disease (YEL-AVD), previously described as multiple-organ system failure, is another rare serious adverse event associated with vaccination. The relationship between YF vaccination and these subsequent illnesses is not well understood. The incidence of YEL-AND and YEL-AVD has been estimated at 0.8 cases/100,000 doses administered and 0.4 cases/100,000 doses administered, respectively.[40] However, the incidence of each appears to increase with advancing age.

Because it is a live vaccine, it is contraindicated in immunocompromised patients, including symptomatic HIV-infected patients or those with CD4+ cells less than 200/mm^3 (0.2×10^9/L), patients with malignant neoplasms, patients on immunosuppressant therapy, and children younger than 6 months. A history of thymic dysfunction is now also regarded as a contraindication due to an apparent association with YEL-AVD.[1] The vaccine should be used with caution in children 6 to 8 months of age, patients 60 years of age and older, asymptomatic HIV-infected patients with CD4+ cells between 200 and 499/mm^3 (0.2×10^9 and 0.499×10^9/L), pregnancy, and during breastfeeding. An additional precaution is used in patients with latex allergies because the vial stopper is made of latex.[62]

According to the International Health Regulations, YF vaccine must be administered only at certified YF vaccination centers.[1] Within the United States, state and territorial health departments have the authority to designate nonfederal vaccination centers. Most other countries use governmental-affiliated clinics to provide official YF vaccinations. Under International Health Regulations, any country may require proof of YF vaccination from travelers coming from countries with YF activity, even if travelers stop in a country to connect flights. A few countries (mostly in Africa) require proof of vaccination from all arriving travelers. Travelers must allow a minimum of 10 days from vaccination to country entry. Proof of vaccination must be in the form of a signed and stamped International Certificate of Vaccination or Prophylaxis.[1] The same form can be used as a waiver to document that a patient has a contraindication to receiving YF vaccination. Each country may have its own entry requirements. For example, some countries may require a YF vaccine booster at 10 years. Global travelers should check health-related entry requirements for each country they plan to visit. This information can be obtained from travel medicine consultants, foreign embassies, or governmental websites. An informed traveler is less likely to experience quarantine, refusal of entry, or vaccination in country.[1]

Tick-Borne Infections. Ticks are small hematophagous arthropods that can introduce parasites, bacteria, or viruses into vertebrates.[63] After mosquitoes, ticks are the next most common vector for transmitting human infectious diseases worldwide. In North America and Eurasia, they are actually the most common vectors. Some of the most common tick-borne infections that travelers may encounter outside of the United States are *Borrelia burgdorferi* (Lyme borreliosis), *Borrelia* spp. (tick-borne relapsing fever), *Rickettsia africae* (African tick bite fever), tick-borne encephalitis virus (TBEV; European encephalitis), *Rickettsia conorii* (Mediterranean spotted fever), *Francicella tularensis* (tularemia), and *Babesia* spp. (babesiosis).[63] While antimicrobial therapies are available to treat most of the bacterial and protozoal pathogens, prevention is the best strategy to protect travelers from unwanted infections and complications.[1,38]

Travelers spending time in outdoor environments with tick activity should wear protective clothing, and apply DEET to unprotected skin.[38] Clothing can also be sprayed with the acaricide permethrin. Daily self-inspection is important to identify ticks early. Proper tweezer removal should be performed if ticks are found to be attached to the skin.

There are no effective treatments for TBEV, but vaccines are available outside the United States. These vaccines are often recommended for campers, hikers, or occupational workers who are likely to be exposed to ticks in the TBEV regions of Europe and Asia.[1]

Rabies. Rabies, a noninsect vector-borne infection, is an important life-threatening infection, which causes more than 60,000 deaths annually.[64] Certain wild mammals are referred to as high-risk "rabies vector species" such as raccoons, foxes, skunks, bats, and groundhogs. However, humans traveling in the developing world are more likely to contract the infection from domestic-appearing vectors, like dogs.[65] In these parts of the world, it is not uncommon to see dogs, cats, and monkeys on the streets or in tourist areas. Postexposure bite management is identical to wild and domestic exposures. The affected site should be cleaned immediately with soap and water, and then victims should be assessed for postexposure prophylaxis.[1] Unfortunately, access to quality rabies vaccine and immune globulin may be a challenge for global travelers, especially in remote areas.[4,66] In some countries, pharmaceutical quality standards may not be as high as in developed countries. In addition, supplies of available rabies products at local medical facilities may be counterfeit or poorly stored (subject to temperature variations).[1] With such a high mortality risk, exposed individuals, especially in small towns and villages, may require medical evacuation to reliable hospitals with adequate supplies of quality vaccines and immune globulin.

Respiratory-Transmitted Infections

Tuberculosis is one of the most common infectious diseases in the developing world. Travelers to developing countries can be easily exposed to infected persons with contagious "active" forms of the disease.[67] The CDC advises travelers to "avoid exposure to tuberculosis (TB) patients in crowded environments (such as hospitals, prisons, or homeless shelters)."[1] Travelers providing care to such patients should consider the use of personal protective devices, such as N-95 masks. TB infection is discussed in Chapter 135, "Tuberculosis."

Influenza is another important global infection concern. There are concerns about pandemic avian influenza epidemics occurring in the future.[4,68] Fortunately, human-to-human cases are unlikely. Global travelers should avoid markets and farms where live poultry is sold or raised and avoid contact with dead poultry, chicken blood, or undercooked chicken in avian influenza-affected areas.[1] Influenza is discussed in Chapter 131, "Influenza."

Middle East Respiratory Syndrome Coronavirus (MERS-CoV) is responsible for a severe illness that was first reported in Saudi Arabia in 2012 and has since spread to several other regions, including North America.[69] Common symptoms include severe acute respiratory illness including fever, cough, and shortness of breath. Mortality rates have been 30% to 40% among patients with laboratory-confirmed infection.[70] All reported cases have been linked to countries in and near the Arabian Peninsula. There are no antiviral medications to treat MERS-Co-V nor there are vaccines to prevent MERS-CoV infection at present time. Risk avoidance strategies in endemic areas include good hand hygiene, avoiding contact with sick people, and avoiding contact with camels and raw or uncooked camel milk or meat.[1,69]

Two vaccine-preventable infections that should be assessed as part of pretravel consultation are measles and meningococcal infections. Most travelers have immunity against measles, but an assessment of vaccine history with consideration of measuring titers should be part of a pretravel consultation. Widespread vaccination against *Neisseria meningitidis* is less likely than measles. Persons traveling to high-risk areas like the "meningitis belt" of sub-Saharan Africa should also be assessed for immunity.[1] These vaccine-preventable illnesses are discussed in greater detail in Chapter 147, "Vaccines, Toxoids, and Other Immunobiologics."

Neglected Tropical Diseases

Neglected tropical diseases are infectious diseases that are found in some of the poorest tropical regions of the world and have not been considered a priority by funding agencies, pharmaceutical companies, or global policymakers.[71] These diseases rarely cause infection among global travelers from more developed countries unless they spend significant time in high-risk areas. Some of the more common diseases in this category are leishmaniasis, trypanosomiasis (Chagas and African), schistosomiasis, ascariasis, lymphatic filariasis, hookworm infection, and dracunculiasis (Guinea worm). Interested readers can learn more about these in the CDC Yellow book[1] or in Chapter e138.

Sexually Transmitted Infections

Global travel has long been linked with STIs. Global travelers may alter their behavior patterns as they leave their "normal environment." Travelers may give into hedonistic tendencies, especially if they use alcohol and illicit drugs. Travelers may behave with increased promiscuity when in exotic places, including sexual activity with commercial sex workers.[72] Global travelers taking part in risky (unprotected) sexual activity put themselves at risk for infections such as syphilis, gonorrhea, chlamydia, HIV, and hepatitis B (see Chapters 140, "Sexually Transmitted Diseases" and 148, "Human Immunodeficiency Virus").

Miscellaneous Travel Infections

Ebola virus belongs to the family of filoviruses and causes a viral hemorrhagic fever. Ebola can be spread through direct contact with the blood or body fluids of an infected person through broken skin or mucous membranes in the eyes, nose, mouth, or other areas.[73] Ebola has long been feared because of its ability to spread with an insidious incubation period of up to 21 days. There have been at least 20 recognized outbreaks of Ebola, all occurring in Africa. Estimated fatality rates have been between 25% and 90%.[75] The largest Ebola outbreak in West Africa in 2014 attracted worldwide attention. Healthcare workers from around the globe went to the region to assist, and many of them contracted the virus and died.[74]

Noninfectious Diseases

Altitude Sickness

Altitude sickness or high-altitude illnesses (HAI) result when the partial pressure of oxygen in the inspired air is lower than that to which the patient is accustomed. Three main syndromes can develop from high-altitude exposure: (1) acute mountain sickness (AMS), (2) high-altitude cerebral edema (HACE), and (3) high-altitude pulmonary edema (HAPE). These different manifestations depend upon the terminal altitude, the rate of ascent, the time spent at maximum altitude, and the altitude when sleeping. The reduction in oxygen inspired over short periods leads to physiologic changes that place stress on the body and may lead to severe illness and even death.[75,76,77,78] Patients who are exposed to reduced oxygen concentrations gradually can compensate. This process is called acclimatization. However, when individuals ascend too rapidly, they will experience a characteristic set of symptoms.[79]. An individual who ascends too rapidly will begin to hyperventilate, become tachycardic, and could experience other symptoms (eg, dizziness, confusion, fatigue). These can be early signs that an individual may be ascending too rapidly and would be at risk for AMS.

The diagnostic symptomatology for AMS includes headache combined with one of the following symptoms: anorexia, nausea or vomiting, fatigue, insomnia, or dizziness.[79] If the appropriate steps are not taken to treat or abate the progression of AMS, the individual could deteriorate further and develop HACE. This deterioration can occur in as little as 12 hours and could subsequently lead to death from vasogenic edema and decreased cerebral perfusion. The signs and symptoms of HACE are ataxia, seizures, slurred speech, neurologic deficits (rare), altered mentation, and decreased consciousness. Decreased consciousness and cerebellar ataxia are the most useful signs in identifying HACE.[79] Although patients may present with pulmonary edema in addition to central nervous system effects, patients may also present only with pulmonary edema. HAPE presents as increased breathlessness upon exertion and progresses to increased breathlessness during rest with weakness and cough. HAPE is due to a noncardiogenic, hydrostatic pulmonary edema.[80] Individuals who ascend to high altitude will experience some degree of hypoxic pulmonary vasoconstriction that leads to pulmonary hypertension and increased capillary pressure in patients who are susceptible to HAPE. HAPE has the potential to be more rapidly fatal than any of the other HAIs.[76-85]

⑨ The mainstay of therapy in all altitude-related illnesses is descent to a lower altitude (typically at least a 300-m reduction in altitude). The administration of oxygen is an appropriate adjunct in severe cases and potentially is an option in mild cases. Due to the lack of availability in the field and the repercussions of mismanagement of deteriorating cases, oxygen therapy is not a likely option for treatment until the patient can descend to a base station with supplies.

Several medications have shown benefit in treating or preventing HAI and could be used as adjunctive therapy to decent and oxygen therapy.[76,80,81]

Acetazolamide has been used for many years for the treatment and prevention of AMS and HACE. Acetazolamide is a carbonic anhydrase inhibitor that reduces hydrogen ion secretion in the proximal renal tubules and increases renal excretion of sodium, potassium, bicarbonate, and water leading to metabolic acidosis. This metabolic acidosis leads to compensatory hyperventilation and increased oxygenation of the blood. This mechanism facilitates the acclimatization process and quickly improves AMS and HACE. Due to its sulfonamide chemical structure, individuals with documented allergies to sulfonamides should avoid acetazolamide.[76-78,82,84,87] One side effect of acetazolamide, which is a potential issue for travelers who plan to have a rapid ascent to high altitude, is muscle fatigue. Carbonic anhydrase inhibitors as a class can cause fatigue but variations between individual agents exist. Methazolamide causes less muscle fatigue after exercise and may have a place in therapy or prevention of altitude sickness.[83]

Some inhaled medications have shown benefits in the prevention of AMS at 72 hours of exposure to high altitude. Inhaled salbutamol/ipratropium (a beta-2 agonist/anticholinergic combination) may have the most benefit in the prevention of AMS. The dose that was used in clinical studies is 3 mg/0.5 mg of salbutamol/ipratropium twice daily for 3 days during the time at high altitudes. Of the other medications tested, inhaled budesonide, a corticosteroid, showed moderate benefit in reducing the effects of AMS but was unsuccessful at preventing AMS.[84] Along with reducing the effects of AMS, Inhaled budesonide may also reduce the incidence of mild AMS; however, that same effect has not been demonstrated for severe AMS.[85]

Dexamethasone is a corticosteroid alternative to acetazolamide in the treatment and prevention of AMS, HACE, and even HAPE. Once initiated, dexamethasone should not be discontinued at altitude prior to acclimatization due to the possibility of rebound cerebral and pulmonary edema. The mechanism by which dexamethasone provides benefit in patients with AMS, HACE, and HAPE has not been well established but is thought to act through its anti-inflammatory properties and antagonism of vascular endothelial growth factor.[78,82,83]

Nifedipine is a calcium channel antagonist that has proven efficacy for the treatment of HAPE. Nifedipine causes pulmonary arterial vasodilation, which improves alveolar fluid clearance and oxygenation of the blood. Reduced pulmonary artery pressure and pulmonary vascular resistance contribute to the positive effects of nifedipine on HAPE.[78-80]

Phosphodiesterase-5 inhibitors (evidence exists for sildenafil and tadalafil) are effective in preventing HAPE, but there is a paucity of studies regarding their use as monotherapy for the treatment of HAPE. Although evidence for the treatment of HAI does not exist for vardenafil, it would likely have the same beneficial effect as prophylaxis given its mechanism of action. The theoretical concern that these agents have a risk for systemic hypotension is present; however, the clinical relevance of this risk in healthy populations without medication interactions is questionable.[75,79,86]

Opioid analgesics should be avoided in individuals who will be ascending to high altitude (or even in individuals ascending to a higher relative altitude prior to acclimatization) due to their ability to reduce the hypoxic ventilator response.[79]

Several nonpharmacologic modalities for the prevention of AMS have shown varied benefits. Pre-ascent staging for 2 days at a high altitude below that of the final targeted altitude showed decreased incidence when compared to a direct ascent control group.[87] This further supports the importance of gradual ascent and acclimatization when planning ascent to high altitude. Another modality that was studied is the use of expiratory resistance devices to create positive expiratory pressure. This was shown to improve oxygen saturation in hypobaric hypoxic environments and would provide a noninvasive way to improve oxygenation during ascent and potentially prevent or delay the onset of AMS.[88]

Jet Lag

Jet lag is a syndrome that develops when travelers cross one or more time zones and are unaccustomed to the new time zone. This syndrome can be characterized by fatigue, malaise, and a disorganized sleep-wake cycle that can lead to poor performance and gastrointestinal distress. The syndrome is created by misaligning an individual’s normal activity schedule with their circadian rhythm. The main treatment for jet lag is to realign the circadian rhythm with the new schedule.[89] The use of natural methods for adjusting circadian rhythms, such as sunlight exposure, phototherapy, or pretravel sleep schedule modification, is typically inexpensive, easy to administer, and provides good outcomes.[89] Adjustment of a sleep schedule prior to travel may be difficult depending on the individual’s normal habits and the destination of their travel. As the number of time zones increases, the difficulty of adjustment of sleep schedule also increases. This is also true regarding the severity of jet lag experienced. Other treatment modalities, such as supplemental melatonin, may provide a more flexible treatment method.[89-91]

In the majority of double-blind, placebo-controlled trials, melatonin was beneficial for the treatment of jet lag.[92] Melatonin is produced endogenously by the pineal gland and is essential in the regulation of circadian rhythms. Positive effects on the quality of sleep were seen when patients were given melatonin prior to sleep. The dosing range varies among studies but doses from 0.5 to 8 mg appear to have equal efficacy.[93] Melatonin also has some hypnotic effects and can aid in the initiation of sleep. Melatonin's status as a dietary supplement lends to it being readily available, and the known side effects of melatonin are relatively mild (eg, dizziness, enuresis, headache, and nausea). There is also no definitive evidence of toxicity associated with high dosages of melatonin.[1,89,94-96]

Sedative hypnotics, such as benzodiazepines and other medications that agonize the benzodiazepine receptors, are also effective at initiation of sleep and maintenance of sleep, but have inherent drawbacks to their use. Although safe to use in most patients, cognition and alertness can be impaired after benzodiazepine-induced sleep. They are also potentially habit forming and should be reserved for severe cases that are not effectively managed with light therapy and melatonin.[89,90] Stimulants, such as modafinil or amphetamines, can be used to increase alertness and performance during the adjustment period after travel if the patient's daily life or performance at work is impaired. Side effect profiles, drug–drug interactions, and abuse potential also limit their utility for regular use.[89]

Traveler's Thrombosis

Traveler's thrombosis, also referred to as travel-associated venous thromboembolism (TAVTE), can occur in otherwise healthy individuals who are not known to be hypercoagulable. Individuals traveling for multiple hours in confined spaces that limit ambulation are at particular risk for thrombosis. Other risk factors for traveler's thrombosis include personal height less than 63 in. (160 cm) and height over 75 in. (190 cm) in individuals traveling by air.[97] Those who are less than 63 in. (160 cm) will likely be unable to place their feet firmly on the floor during the flight and may experience increased pressure on the popliteal vein. This pressure contributes to the development of venous stasis, which is one of Virchow's classic triad of risk factors for VTE. Individuals over 75 in. (190 cm) in height are more likely to be restricted from movement when in a standard seat. This restriction could limit blood flow and also cause venous stasis. Other factors shown to increase the risk of TAVTE are genetic predispositions to clotting (Factor V Leiden), obesity, and oral contraceptive use.[96-98]

Although the increased fluid intake is helpful for preventing TAVTE, scientific evidence does not support this theory.[99] However, this should not dissuade passengers from staying well hydrated. While hydration may have no direct beneficial effect on prevention of traveler's thrombosis, the need to urinate may prompt the individual to ambulate to the restroom. Average healthy urine production ranges from 40 to 80 mL/hr, and the adult bladder capacity ranges from 300 to 400 mL. The urge to void usually occurs when the bladder is one-quarter full. This would mean that assuming normal hydration the average healthy traveler would be prompted to urinate every 1 to 2 hours. Ambulation and the use of lower extremity muscles, by isometric exercises performed during long-haul travel, are the best known ways to prevent VTE and traveler's thrombosis. Compressions stockings reduce asymptomatic clots when appropriately fitted.[100] Compression stockings that have not been custom fitted or appropriately sized do not add any additional protection and in some cases could cause more issues. Pharmacologic prophylaxis is not warranted in most situations and should be avoided due to an increased risk of major bleeding. Patients who have previously been diagnosed with VTE, undergone recent major surgery, or have known malignancy are at high risk of VTE without the added impact of confined travel and therefore should be considered on an individual basis for pharmacologic prophylaxis.[22] The use of aspirin for prevention of traveler's thrombosis is not supported by the literature and should not be recommended for prophylaxis in travelers.[97,98]

Mental Health

Travel, whether short or long, exposes the traveler to both physical and mental stress. Traveling into regions with disrupted personal routines and unfamiliar environmental and cultural elements can make assimilation difficult. This process of exposure and reaction to a different culture has been referred to as acculturation or "culture shock."[101] Controlled psychiatric illnesses and undiscovered predispositions to mental illness may be induced by exposure to these stressful situations. Pretravel screening and education are essential for travelers who are going to be abroad for a substantial amount of time. Patients with a history of mental illness should be counseled on the need for an adequate medication supply and impeccable adherence while abroad.

⑩ The most common psychiatric reason for evacuation from an international trip is depression.[102] Patients who have previously been diagnosed with depression should continue their prescribed medications and minimize alcohol consumption while traveling. Nearly all psychiatric illnesses that are experienced while traveling require treatment with medication.[102] Proper preparation for the trip will reduce the difficulties associated with acquiring appropriate medications and medical care. Given the propensity for exacerbations of mental illness while traveling internationally and the possibility of suicide due to untreated or unrecognized depression, it is prudent to purchase travel insurance that includes medical evacuation coverage and coverage for repatriation of remains. The costs associated with medical evacuation can be high, and travel insurance is typically quite affordable in comparison.[101,102]

Healthcare Outreach

Global Health Organizations and Nongovernmental Organizations

Global health organizations provide many services to developing and developed countries along with information and education resources. Guidance to travelers regarding issues they may encounter while in country is one of these services. From travel advisories to health emergencies, organizations like the WHO provide timely information and guidance for the prevention of illnesses that could lead to significant morbidity or mortality. Many countries have organizations similar to the WHO that serve the country in which they are based. These organizations also provide guidelines and statistical information regarding travel and disease in their specific impoverished areas.[103]

Nongovernmental organizations (NGOs) are nonprofit, voluntary citizens' groups that organized on a local, national, or international level.[104] They provide substantial quantities of quality medical care to patients throughout developing countries.[104] Due to NGOs' contributions to the impoverished population's care, they have established themselves as a major contributor to improving the health of individuals who would normally not have access to quality healthcare. These contributions improve the quality and quantity of life in developing countries.[104]

Medications and Supplies for Medical Missions and Outreach

Providing medical services in other countries requires supplies similar to those used in the country of origin. There is a varied approach to the regulation of medications in different parts of the world. There are concerns with the acquisition and use of medications in these countries that must be considered. Many countries do not have an organization that regulates the standards for the purity and the quality of the products that are distributed. Consequently, medications acquired abroad could be impure or contain varied amounts of the active medication.[104] Due to this variability, it is advisable to obtain medications in the origin country or from a company that has a good reputation for standardization and quality. Medication costs also differ among countries, and the cost could be lower or higher depending on site-specific factors. Medications that undergo quality and safety checks are typically more expensive due to the time required to validate the methods and verify product quality. In many parts of the developing world, medication acquisition is as simple as walking into a pharmacy and requesting the medication with or without a prescription.[14]

The transport of medications into a country may require significant documentation regarding the origin of the medication, visual inspection of the product, and potential taxation. Legal regulations of medications also vary significantly. Seizure of supplies by customs agents could lead to fines and cancellation of the planned provision of medical care. Researching custom law of the destination country is vital to facilitate the entrance and exit of the country. Many organizations have paid employees that deal with this aspect of the trips to ensure there are no issues. However, this may be a role for pharmacists given their product knowledge and versatility.[14]

SELF-ASSESSMENT QUESTIONS

1. Which one of the following actions should not be part of a pretravel health consultation?

A. Conduct a medical history

B. Prescribe or recommend empiric antibiotic for symptomatic traveler's diarrhea

C. Assess the risk of malaria at the traveler’s destination

D. Provide travelers insurance or medical evacuation insurance

2. Which one of the following vaccines requires an International Certificate of Vaccination?

A. Dengue vaccine

B. Injectable polio vaccine

C. Japanese encephalitis vaccine

D. Yellow fever vaccine

3. A 55-year-old man who is HIV positive comes to travel clinic to get vaccinated before traveling to Malaysia. His current CD4+ cell count was 140 cells/mm^3 (0.14 × 10^9/L). Which vaccine would be relatively contraindicated because of the risk of causing an infection?

A. Hepatitis A vaccine

B. DtaP

C. Varicella zoster (live)

D. Inactivated Influenza vaccine

4. Which one of the following statements is FALSE regarding dengue?

A. Humans can get infected in urban areas.

B. Infection with serotype 1 provides protection against the other three serotypes.

C. Acetaminophen is preferred over ibuprofen as an antipyretic agent.

D. The critical phase of illness often involves plasma leakage.

5. While preparing a medical kit for travel to Thailand, a traveler notes that there have been increased reports of norfloxacin-resistant *Campylobacter* in the region he plans to travel. His first-line antibiotic for empiric treatment of traveler’s diarrhea should be:

A. Azithromycin

B. Bismuth subsalicylate

C. Ciprofloxacin

D. Metronidazole

E. Antibiotics should never be used to empirically treat traveler’s diarrhea

6. Which antimalarial prophylactic agent carries the strongest safety warning about use in pregnant travelers?

A. Chloroquine

B. Doxycycline

C. Mefloquine

D. Atovaquone-proguanil

7. This group of travelers frequently encounter higher rates of illness when traveling to tropical or developing regions when compared to general traveler populations:

A. Women aged 40 to 50 years

B. Immigrant travelers visiting friends and relatives back in native countries

C. Travelers with limited healthcare coverage

D. Study abroad students

8. All of the following are advisable methods for limiting mosquito-borne infection in high-risk areas except:

A. Applying 10% DEET repellent on a daily basis

B. Using insecticide-treated bed netting

C. Wearing protective clothing that limits access to human skin

D. Spraying clothing with insect repellant or insecticide

9. This vector-borne infection has become endemic in Central America, South America, and the Caribbean since 2015 and a majority of infected patients have symptoms.

A. Japanese encephalitis

B. Hepatitis A

C. Chikungunya

D. Dengue

E. Typhoid

10. The first-line treatment for all high-altitude illnesses is:

A. Nifedipine

B. Hydration

C. Descent

D. Melatonin

E. Dexamethasone

11. If a patient reports having had anaphylaxis to sulfa drugs, which one of the following altitude sickness medications would carry the highest risk for hypersensitivity?

A. Sildenafil

B. Acetazolamide

C. Acebutolol

D. Nifedipine

E. Oxycodone

12. The following medication would be the most appropriate treatment to adjust circadian rhythms in patients with jet lag who cannot adjust their sleep patterns prior to travel.

A. Modafinil

B. Melatonin

C. Clonidine

D. Diazepam

E. Zolpidem

13. Which of the following risks lead to traveler's thrombosis specifically in patients >75 in. (190 cm) tall?

A. Popliteal vein compression

B. Inability to recline

C. Restricted movement in a standard seat

D. Decreased venous valves

E. Reduced need to ambulate

14. The most cost-effective approach for VTE prevention on long-haul airline trips is:

A. Ambulation with isometric exercises

B. Aspirin

C. Compression stockings

D. Low molecular weight heparin

15. Which of the following is the most common psychiatric reason for evacuation from international travel?

A. Generalized anxiety disorder

B. Schizophrenia

C. Agoraphobia

D. Mania

E. Depression

SELF-ASSESSMENT QUESTION-ANSWERS

1. **D**. From the "Pretravel Preparation" section: Provision or sales of insurance is not an integral part of pretravel health consultation. All other items listed are important parts of pretravel health consultation. Travelers can be provided with information on where to get travel insurance and names of insurers.

2. **D.** From the "Yellow Fever" section: Under International Health Regulations, any country may require proof of YF vaccination from travelers coming from countries with YF activity, even if travelers stop in a country to connect flights. A few countries (mostly in Africa) require proof of vaccination from all arriving travelers. Proof of vaccination must be in the form of a signed and stamped International Certificate of Vaccination or Prophylaxis. This is the only vaccine listed that requires this.

3. **C.** Varicella is the only live vaccine listed here. From the “Immunocompromised Travelers” section: Live vaccines are generally contraindicated where the benefit versus risk must be considered in immunocompromised patients.

4. **B.** From the “Dengue” section: Patients subsequently infected with a different serotype may actually develop an extremely severe secondary infection which is triggered by an immune response in the presence of cross-reactive non-neutralizing antibodies.

5. **A.** From the “Diarrheal Illness” section: Current recommendations for antibiotic therapy are for single-dose or short-course fluoroquinolones or azithromycin. Azithromycin may now be preferred in south or southeastern Asia because of increased presence of fluoroquinolone-resistant *Campylobacter*.

6. **B.** From the “Pregnant Travelers” section: Doxycycline is contraindicated because of bone and teeth development.

7. **B.** From thr “Pretravel Preparation” section: VFR travelers often display some of the highest rates of travel health problems.

8. **A.** From the “Vector-Borne Infections” section: DEET needs to be 20% to 50% to provide the best effectiveness in high-risk areas.

9. **C.** From the “Chikungunya” section: The number of suspected or confirmed cases of chikungunya has now reached 1.74 million in the Americas, with about 80% of CHIKV infections come from six countries (Dominican Republic, Colombia, El Salvador, Guadeloupe, Honduras, and Martinique). Only about 3% to 28% of people infected with CHIKV remain asymptomatic.

10. **C.** From the “Altitude Sickness” section: The mainstay of therapy in all altitude-related illnesses is descent to a lower altitude.

11. **B.** From the “Altitude Sickness” section: Due to its sulfonamide chemical structure, individuals with documented allergies to sulfonamides should avoid this medication.

12. **B.** From the “Jet Lag” section: Melatonin is produced endogenously by the pineal gland and is essential in the regulation of circadian rhythms.

13. **C.** From the “Traveler’s Thrombosis” section: Those individuals who are over 75 in. (190 cm) are more likely to be restricted from movement when in a standard seat.

14. **A.** From the “Traveler’s Thrombosis” section: Ambulation and the use of lower extremity muscles, by isometric exercises performed during long-haul travel, are the best-known ways to prevent VTE and traveler’s thrombosis. Obviously no costs are associated with this activity.

15. **E.** From the “Mental Health” section: The most common psychiatric reason for evacuation from an international trip is depression.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e >

Chapter e20: Pediatrics: General Topics in Pediatric Pharmacotherapy

Milap C. Nahata; Carol Taketomo

KEY CONCEPTS

KEY CONCEPTS

① Children are not just “little adults,” and lack of data on important pharmacokinetic and pharmacodynamic differences has led to several disastrous situations in pediatric care.

② Variations in absorption of medications from the gastrointestinal tract, intramuscular injection sites, and skin are important in pediatric patients, especially in premature and other newborn infants.

③ The rate and extent of organ function development and the distribution, metabolism, and elimination of drugs differ not only between pediatric versus adult patients but also among pediatric age groups.

④ The effectiveness and safety of drugs may vary among age groups and from one drug to another in pediatric versus adult patients.

⑤ Concomitant diseases may influence dosage requirements to achieve a targeted effect for a specific disease in children.

⑥ Use of weight-based dosing of medications for obese children may result in suboptimal drug therapy.

⑦ The myth that neonates and young infants do not experience pain has led to inadequate pain management in this pediatric population.

⑧ Special methods of drug administration are needed for infants and young children.

⑨ Many medicines needed for pediatric patients are not available in appropriate dosage forms; thus, the dosage forms of drugs marketed for adults may require modification for use in infants and children, necessitating assurance of potency and safety of drug use.

⑩ The pediatric medication-use process is complex and error prone because of the multiple steps required in calculating, verifying, preparing, and administering doses.

BEYOND THE BOOK

BEYOND THE BOOK

Visit the US Food and Drug Administration website and navigate to the New Pediatric Labeling Information Database <https://www.accessdata.fda.gov/scripts/sda/sdNavigation.cfm?sd=labelingdatabase>. The website provides comprehensive up-to-date information related to pediatric drug labeling changes. Explore available drugs, review recent labeling information for one drug of interest, and summarize the label changes. This website is useful to enhance student understanding of available resources for pediatric drug dosing information.

INTRODUCTION

Remarkable progress has been made in the clinical management of diseases in pediatric patients. This chapter highlights important principles of pediatric pharmacotherapy that must be considered when the diseases discussed in other chapters of this book occur in pediatric patients, defined as those younger than 18 years. Newborn infants born before 37 weeks of gestational age may experience a variety of health problems and are termed *premature;* those between 1 day and 1 month of age are *neonates;* 1 month to 1 year are *infants;* 1 to 11 years are *children;* and 12 to 16 years are *adolescents.* This chapter covers notable examples of problems in pediatrics, pharmacokinetic differences in pediatric patients, drug efficacy and toxicity in this patient group, and various factors affecting pediatric pharmacotherapy. Specific examples of problems and special considerations in pediatric patients are cited to enhance understanding.

① Infant mortality up to 1 year of age has declined from 200 per 1,000 births in the 19th century to 75 per 1,000 births in 1925 and to 5.6 per 1,000 births in 2019.[1] This success has resulted largely from improvements in identification, prevention, and treatment of diseases once common during delivery and the infancy period. Although most marketed drugs are used in pediatric patients, less than one-half of the drugs approved by the US Food and Drug Administration (FDA) are labeled for use in the pediatric population. Data on the pharmacokinetics, pharmacodynamics, efficacy, and safety of drugs in infants and children are scarce. Lack of this type of information led to disasters such as gray baby syndrome from chloramphenicol, phocomelia from thalidomide, and kernicterus from sulfonamide therapy. Gray baby syndrome was first reported in two neonates who died after excessive doses of chloramphenicol (100-300 mg/kg/day); the serum concentrations of chloramphenicol immediately before death were 75 and 100 μg/mL (mg/L; 232 and 309 μmol/L). Patients with gray baby syndrome usually have abdominal distension, vomiting, diarrhea, a characteristic gray color, respiratory distress, hypotension, and progressive shock.

Thalidomide is well known for its teratogenic effects. Clearly implicated as the cause of multiple congenital fetal abnormalities (particularly limb deformities), thalidomide also can cause polyneuritis, nerve damage, and mental retardation. Isotretinoin (Accutane) is another teratogen, because it is used to treat severe acne vulgaris, which is common in teenage patients who may be sexually active but not willing to acknowledge that activity to healthcare professionals; isotretinoin has presented a difficult problem in patient education since its marketing in the 1980s.

Kernicterus was reported in neonates receiving sulfonamides, which displaced bilirubin from albumin-binding sites in the blood to cause hyperbilirubinemia. This results in deposition of bilirubin in the brain and induces encephalopathy in infants.

Another area of concern in pediatrics is identifying an optimal dosage. Dosage regimens cannot be based simply on body weight or surface area of a pediatric patient extrapolated from adult data. Bioavailability, pharmacokinetics, pharmacodynamics, efficacy, and safety information can differ markedly between pediatric and adult patients, as well as among pediatric patients, because of differences in age, organ function, and disease state. Significant progress has been made in the area of pediatric pharmacokinetics during the past two decades, but few such studies have correlated pharmacokinetics with the outcomes of efficacy, adverse effects, or quality of life.

Several additional factors should be considered in optimizing pediatric drug therapy. Many drugs prescribed widely for neonates, infants, and children are not available in suitable dosage forms. For example, extemporaneous liquid dosage forms of amiodarone, baclofen, captopril, hydroxyurea, tacrolimus, ursodiol, and spironolactone are prepared for infants and children who cannot swallow tablets or capsules, and injectable dosage forms of aminophylline, methylprednisolone, morphine, and phenobarbital are diluted to accurately measure small doses for neonates and infants. Alteration (dilution or reformulation) of dosage forms intended for adult patients raises questions about the bioavailability, stability, and compatibility of these drugs. Because of low fluid volume requirements and limited access to IV sites, special methods must be used for delivery of IV drugs to infants and children. As simple as it may seem, administration of oral drugs to young patients continues to be a difficult task for nurses and parents. Similarly, ensuring adherence to pharmacotherapy in pediatric patients poses a special challenge.

Finally, the need for additional pharmacologic or therapeutic research brings up the issue of ethical justification for conducting research. Investigators proposing studies and institutional review committees approving human studies must assess the risk-to-benefit ratio of each study to be fair to children who are not in a position to accept or reject the opportunity to participate in the research project.

Enormous progress in pharmacokinetics has been made in pediatric patients. Two factors have contributed to this progress: (a) the availability of sensitive and specific analytic methods to measure drugs and their metabolites in small volumes of biologic fluids and (b) awareness of the importance of clinical pharmacokinetics in optimization of drug therapy. Absorption, distribution, metabolism, and elimination of many drugs are different in premature infants, full-term infants, and older children, and this topic is discussed in detail in the next few sections.

ABSORPTION

Gastrointestinal Tract

②Two factors affecting the absorption of drugs from the gastrointestinal tract are pH-dependent passive diffusion and gastric emptying time. Both processes are strikingly different in premature infants compared with older children and adults. In a full-term infant, gastric pH ranges from 6 to 8 at birth but declines to 1 to 3 within 24 hours.[2] In contrast, gastric pH remains elevated in premature infants because of immature acid secretion.[3]

In premature infants, higher serum concentrations of acid-labile drugs, such as penicillin,[4] ampicillin,[5] and nafcillin,[6] and lower serum concentrations of a weak acid such as phenobarbital[7] can be explained by higher gastric pH. Because of a lack of extensive data comparing serum concentration–time profiles after oral versus IV drug administration, differences in the bioavailability of drugs in premature infants are poorly understood. Although little is known about the influence of developmental changes with age on drug absorption in pediatric patients, a few studies with drugs (eg, digoxin and phenobarbital) and nutrients (eg, arabinose and xylose) have suggested that the processes of both passive and active transport may be fully developed by approximately 4 months of age.[8] Little is known about the development and expression of the efflux transporter P-glycoprotein and the intestinal drug-metabolizing enzymes and microflora, and their impact on drug absorption and bioavailability in infants and children.

Studies have shown that gastric emptying is slow in premature infants.[9] Thus, drugs with limited absorption in adults may be absorbed efficiently in premature infants because of prolonged contact time with gastrointestinal mucosa.

Intramuscular Sites

Drug absorption from an intramuscular site may be altered in premature infants. Differences in relative muscle mass, poor perfusion to various muscles, peripheral vasomotor instability, and insufficient muscular contractions in premature infants compared with older children and adults can influence drug absorption from the intramuscular site. The net effect of these factors on drug absorption is impossible to predict; phenobarbital has been reported to be absorbed rapidly,[10] whereas diazepam absorption may be delayed.[11] Thus, intramuscular dosing is used rarely in neonates except in emergencies or when an IV site is inaccessible.

Skin

Percutaneous absorption may be increased substantially in newborns because of an underdeveloped epidermal barrier (stratum corneum) and increased skin hydration. Furthermore, because the ratio of total body surface area (BSA) to total body weight is highest in the youngest group, the relative systemic exposure of topically applied drugs, including corticosteroids, may be higher in infants and young children than in adults. The increased exposure can produce toxic effects after topical use of hexachlorophene soaps and powders,[12] salicylic acid ointment, and rubbing alcohol.[13] Interestingly, a study has shown that a therapeutic serum concentration of theophylline can be achieved for control of apnea in premature infants less than 30 weeks' gestation after topical application of gel containing a standard dose of theophylline.[14] The use of this route of administration may minimize the unpredictability of oral and intramuscular absorption and the complications of IV drug administration for certain drugs. A transdermal patch formulation of methylphenidate has been approved for use in children 6 to 12 years of age for treatment of attention-deficit/-hyperactivity disorder (ADHD). The patch can be applied once daily and can remain on during normal activities such as bathing, swimming, and exercising.

DISTRIBUTION

③Drug distribution is determined by the physicochemical properties of the drug itself (pK_a, molecular weight, and partition coefficient) and the physiologic factors specific to the patient. Although the physicochemical properties of the drug are constant, the physiologic functions often vary in different patient populations. Some important patient-specific factors include extracellular and total body water, protein binding by the drug in plasma, and presence of pathologic conditions modifying physiologic function. Total body water, as a percentage of total body weight, has been estimated to be 94% in fetuses, 85% in premature infants, 78% in full-term infants, and 60% in adults.[14] Extracellular fluid volume also is markedly different in premature infants compared with older children and adults; the extracellular fluid volume may account for 50% of body weight in premature infants, 35% in 4- to 6-month-old infants, 25% in 1-year-old children, and 19% in adults.[15] This conforms to the observed gentamicin distribution volumes of 0.48 L/kg in neonates and 0.20 L/kg in adults.[16] Studies have shown that the distribution volume of tobramycin is largest in the most premature infants and decreases with increases in gestational age and birth weight of the infant.[17]

Binding of drugs to plasma proteins is decreased in newborn infants because of decreased plasma protein concentration, lower binding capacity of protein, decreased affinity of proteins for drug binding, and competition for certain binding sites by endogenous compounds such as bilirubin. The plasma protein binding of many drugs, including phenobarbital, salicylates, and phenytoin, is significantly less in the neonate than in adults.[18] The decrease in plasma protein binding of drugs can increase their apparent volumes of distribution. Therefore, premature infants require a larger loading dose than older children and adults to achieve a therapeutic serum concentration of drugs such as phenobarbital[19] and phenytoin.[20]

The consequences of increased concentrations of free or unbound drug in the serum and tissues must be considered. Pharmacologic and toxic effects are related directly to the concentration of free drug in the body. Increases in free drug concentrations may result directly from decreases in plasma protein binding or indirectly from, for example, drug displacement from binding sites. Increased mortality from the development of kernicterus secondary to displacement of bilirubin from albumin and other serum proteins by sulfisoxazole in neonates is well documented.[21] However, because drug bound to plasma proteins cannot be eliminated by the kidney, an increase in free drug concentration also may increase its clearance.[22]

The amount of body fat is substantially lower in neonates than in adults, which may affect drug therapy. Certain highly lipid-soluble drugs are distributed less widely in infants than in adults. The apparent volume of distribution of diazepam ranged from 1.4 to 1.8 L/kg in neonates and from 2.2 to 2.6 L/kg in adults.[23] In recent years, the number of mothers breastfeeding their infants has climbed. Thus, certain drugs distributed in breast milk may pose problems for the infants. The American Academy of Pediatrics (AAP) recommends that bromocriptine, cyclophosphamide, cyclosporine, doxorubicin, ergotamine, lithium, methotrexate, phenindione, codeine, and all drugs of abuse (eg, amphetamine, cocaine, heroin, marijuana, and phencyclidine) not be used during breastfeeding. Use of nuclear medicines should be stopped temporarily during breastfeeding.[24] Note that these recommendations are based on limited data; other drugs taken over a prolonged period by the mother also may be toxic to the infant. For example, acebutolol, aspirin, atenolol, clemastine, phenobarbital, primidone, sulfasalazine, and 5-aminosalicylic acid have been associated with adverse effects in some nursing infants.[24] Unless the benefits outweigh the risks, the mother should avoid using any drug during pregnancy and while breastfeeding.

METABOLISM

Drug metabolism is substantially slower in infants than in older children and adults. There are important differences in the maturation of various pathways of metabolism which may develop over the weeks, months, or year(s) after birth of a premature infant.[25] For example, the sulfation pathway is well developed, but the glucuronidation pathway is undeveloped in infants.[26] Although acetaminophen metabolism by glucuronidation is impaired in infants compared with adults, it is partly compensated for by the sulfation pathway. The cause of the tragic chloramphenicol-induced gray baby syndrome in newborn infants is decreased metabolism of chloramphenicol by glucuronyltransferases to the inactive glucuronide metabolite.[27] This metabolic pathway is age related[28] and may take several months to 1 year to develop fully, as evidenced by the increase in clearance with age up to 1 year.[29]

Interestingly, higher serum concentrations of morphine are required to achieve efficacy in premature infants than in adults, in part because infants are not able to metabolize morphine adequately to its 6-glucuronide metabolite (20 times more active than morphine).[30] This is balanced to some degree by the fact that the clearance of morphine quadruples between 27 and 40 weeks of postconceptional age.

Metabolism of drugs, such as theophylline, phenobarbital, and phenytoin by oxidation, also is impaired in newborn infants. However, the rate of metabolism is more rapid with phenobarbital and phenytoin than with theophylline, perhaps because of the involvement of different cytochrome P450 (CYP) isozymes. Total clearance of phenytoin by CYP2C9 and, to a lesser extent, by CYP2C19 surpasses adult values by 2 weeks of age, whereas theophylline clearance is not fully developed for several months.[18] Two additional observations about theophylline metabolism by CYP1A2 in pediatric patients should be noted. First, in premature infants receiving theophylline for treatment of apnea, a significant amount of its active metabolite caffeine may be present, unlike the case in older children and adults.[18] Second, theophylline clearance in children 1 to 9 years of age exceeds, the values in infants as well as adults. Thus, a child with asthma often requires markedly higher doses on a weight basis of theophylline compared with an adult.[31] Because of decreased metabolism, daily doses of drugs such as theophylline, phenobarbital, phenytoin, and diazepam should be decreased in premature infants. CYP3A4 is the most commonly expressed enzyme for the metabolism of drugs and it may take up to one year for its full maturation.[25]

The clearance of unbound *S*-warfarin, a substrate of CYP2C9, was substantially greater in prepubertal children than among pubertal children and adults even after adjustment for total body weight.[32] Finally, clearance of caffeine, metabolized by demethylation, declines to adult values when girls reach Tanner stage II (early puberty) and boys reach Tanner stages IV and V (late puberty).[33] The knowledge of pharmacogenetics and pharmacogenomics now is being applied to patient care in some instances. 6-Mercaptopurine (6-MP), a drug commonly used in pediatric leukemias, undergoes metabolism that is facilitated by thiopurine *S*-methyltransferase (TPMT). The inherited deficiency (an autosomal recessive trait), which occurs in 6% to 11% of patients, is primarily explained by three polymorphisms in the *TPMT* gene (**2*, **3A*, and **3C*). Children homozygous for one of the variant alleles require 6-MP dose reduction of approximately 90%, and heterozygotic children need a dose reduction of approximately 50% to achieve survival rates observed in patients receiving full doses in the absence of TPMT deficiency. Thus, *TPMT* screening is recommended to identify patients with genotypes associated with TPMT deficiency who may benefit from dose reductions to prevent toxicity.[34]

ELIMINATION

Drugs and their metabolites are often eliminated by the kidney. The glomerular filtration rate (GFR) may be as low as 0.6 to 0.8 mL/min/1.73 m^2 (0.006-0.008 mL/s/m^2) in preterm infants and approximately 2 to 4 mL/min/1.73 m^2 (0.02-0.04 mL/s/m^2) in term infants. The processes of glomerular filtration, tubular secretion, and tubular reabsorption determine the efficiency of renal excretion. These processes may not develop fully for several weeks to 1 to 2 years after birth. Additional studies are needed about the ontogeny of renal transporters, for example, P-glycoprotein.[25]

Studies in infants have shown that tobramycin clearance during the first postnatal week may increase with an increase in gestational age.[17] In infants up to 1 month after birth, postnatal age also was correlated directly with aminoglycoside clearance.[29] Thus, premature infants require a lower daily dose of drugs eliminated by the kidney during the first week of life; the dosage requirement then increases with age.

Because of immature renal elimination, chloramphenicol sodium succinate can accumulate in premature infants. Although chloramphenicol sodium succinate is inactive, this accumulation may be the reason for an increased bioavailability of the biologically active, chloramphenicol in premature infants compared with older children.[28] These data indicate that dose-related toxicity may result from an underdeveloped glucuronidation pathway as well as increased bioavailability of chloramphenicol in premature infants.

DRUG EFFICACY AND TOXICITY

④Besides the pharmacokinetic differences previously identified between pediatric and older patients, factors related to drug efficacy and toxicity also should be considered in planning pediatric pharmacotherapy. Unique pathophysiologic changes occur in pediatric patients with some disease states.

Examples of pathophysiologic and pharmacodynamic differences are numerous. Clinical presentation of chronic asthma differs in children and adults. Children present almost exclusively with a reversible extrinsic type of asthma, whereas adults have nonspecific, nonatopic bronchial irritability. This explains the value of adjunctive hyposensitization therapy in the management of pediatric patients with extrinsic asthma.[35]

The maintenance dose of digoxin is substantially higher in infants than in adults. This is explained by a lower binding affinity of receptors in the myocardium for digoxin and increased digoxin-binding sites on neonatal erythrocytes compared with adult erythrocytes.[36] Insulin requirements are highest during adolescence because of the individual's rapid growth. Growth hormone therapy has allowed children with growth hormone deficiency to attain greater adult height. However, a study has shown that in "normal" short children (without growth hormone deficiency), early and rapid pubertal progression by growth hormone therapy may lead to a shorter final adult height than may have been attained naturally.[37] This finding emphasizes the need for identifying specific indications for the effective and safe use of drugs in pediatric patients.

Certain adverse effects of drugs are most commonly seen in the newborn period, whereas other toxic effects may not be apparent for a long period of time because of difficulty in assessing extended medication safety. Promethazine now is contraindicated for use in children younger than 2 years because of the risk of severe respiratory depression. Chloramphenicol toxicity is increased in newborns because of immature metabolism and enhanced bioavailability. Codeine toxicity and death have been reported after tonsillectomy and adenoidectomy in children who were ultrarapid metabolizers receiving codeine within the typical dose range.[38] Thus, codeine should not be used in these patients. Similarly, propylene glycol, which is added to many injectable drugs, including phenytoin, phenobarbital, digoxin, lorazepam, vitamin D, and hydralazine, to increase their stability, can cause hyperosmolality in infants.[39] It is also present in formulations of oral drugs, including acetaminophen, diphenhydramine, furosemide, ibuprofen, and prednisone.

Benzyl alcohol was a popular preservative used in intravascular flush solutions until a syndrome of metabolic acidosis, seizures, neurologic deterioration, gasping respirations, hepatic and renal abnormalities, cardiovascular collapse, and death was described in premature infants. A decline in both mortality and the incidence of major intraventricular hemorrhage was documented after use of solutions containing benzyl alcohol was stopped in low-birth-weight infants.[40] It is also used as a preservative in parenteral dexamethasone, methylprednisolone, enoxaparin, midazolam, and multivitamin formulations.

Ethanol is present in certain oral drugs, including phenobarbital and ranitidine, and, sorbitol is used in oral liquids, including diphenhydramine, ferrous sulfate, furosemide, ondansetron, and prednisone. The safe and acceptable levels of intake of many excipients have not been determined for infants and children.

The common cold occurs frequently in infants and children and is often treated with antihistamines, decongestants, antitussives, and expectorants. Given the lack of evidence for their efficacy and serious toxicities associated with overdoses, the FDA issued a public health advisory in 2008 recommending that these drugs not be used in children younger than 2 years. The manufacturers have voluntarily agreed to label these medications not for use in children younger than 4 years.

Tetracyclines are contraindicated for use in pregnant women, nursing mothers, and children younger than 8 years because these drugs can cause dental staining and defects in enamelization of deciduous and permanent teeth, as well as a decrease in bone growth.[41] However, the Centers for Disease Control and Prevention (CDC) has recommended the use of doxycycline for initial prophylaxis after suspected bioterrorism-related exposure to *Bacillus anthracis* (anthrax); the potential benefits outweigh potential risks among infants and children. Certain fluoroquinolones are indicated for infections including inhalation anthrax, complicated urinary tract infections and pyelonephritis, but their use should be restricted due to concern of adverse effects when no safe and effective alternative is available or an oral agent is used as an alternative to parenteral therapy.[42]

Some drugs may be less toxic in pediatric patients than in adults. Aminoglycosides are less toxic in infants than in adults. In adults, aminoglycoside toxicity is related to both peripheral compartment accumulation and the individual patient's inherent sensitivity to these tissue concentrations.[43] Although neonatal peripheral tissue compartments for gentamicin have been reported to closely resemble those of adults with similar kidney function,[16] gentamicin infrequently is nephrotoxic in infants. This dissimilarity in the incidence of nephrotoxicity implies that newborn infants have less inherent tissue sensitivity for toxicity than do adults.

The differences in efficacy, toxicity, and protein binding of drugs in pediatric versus adult patients raise an important question about the acceptable therapeutic range in children. Therapeutic ranges for drugs are first established in adults and often are applied directly to pediatric patients, but specific efficacy and safety studies should be conducted in pediatric patients to define optimal therapeutic ranges of drugs.

FACTORS AFFECTING PEDIATRIC THERAPY

⑤ Because most drugs are either metabolized by the liver or eliminated by the kidneys, liver, and kidney diseases are expected to decrease the dosage requirements in patients. Nevertheless, not all diseases require lower doses of drugs. For instance, patients with cystic fibrosis require larger doses of certain drugs to achieve therapeutic concentrations.[44]

Hepatic Disease

Because the liver is the main organ for drug metabolism, drug clearance usually is decreased in patients with hepatic disease. However, most studies on the influence of hepatic disease on dosage requirements have been performed in adults, and these data may not be extrapolated uniformly to pediatric patients.

Drug metabolism by the liver depends on complex interactions among hepatic blood flow, ability of the liver to extract the drug from the blood, drug binding in the blood, and both type and severity of hepatic disease. Routine hepatic function tests, such as determinations of serum aspartate aminotransferase, serum alanine aminotransferase, alkaline phosphatase, and bilirubin concentrations, have not correlated consistently with drug pharmacokinetics. Furthermore, because of different pathologic changes in various types of hepatic diseases, patients with acute viral hepatitis may have different abilities to metabolize drugs than patients with alcoholic cirrhosis.[45]

On the basis of hepatic extraction characteristics, drugs can be divided into two categories. The first category consists of drugs with a high hepatic extraction ratio (greater than 0.7; such drugs include morphine, meperidine, lidocaine, and propranolol). Clearance of these drugs is affected by hepatic blood flow. Decreased hepatic blood flow in the presence of disease states, such as cirrhosis and congestive heart failure, is expected to decrease the clearance of drugs with high extraction ratios. The second category consists of drugs with a low extraction ratio (<0.2) and a low affinity for plasma proteins. Metabolism of these drugs (eg, theophylline, chloramphenicol, and acetaminophen) is influenced mainly by hepatocellular function and not as much by changes in hepatic blood flow or plasma protein binding. One report suggested that theophylline clearance may decrease by 45% in a child with acute viral hepatitis.[45] Because of a lack of specific data on dosage adjustment in hepatic disease, drug therapy should be monitored closely in pediatric patients to avoid potential toxicity from excessive doses, particularly for drugs with narrow therapeutic indices.

Kidney Disease

Kidney failure decreases the dosage requirement of drugs eliminated by the kidneys. Again, because of limited studies, dosage adjustments in pediatric patients are based largely on data obtained in adults. For many important drugs, such as aminoglycoside antibiotics, renal clearance, or rate of elimination is directly proportional to the GFR, as measured by endogenous creatinine clearance.

In clinical practice, GFR can be estimated from prediction equations, such as the Schwartz formula, which takes into account serum creatinine concentration and the patient's height, gender, and age. The advantage of estimating GFR using the Schwartz equation is rapid determination and the avoidance of a cumbersome 24-hour urine collection.[46,47] The following formula is used to estimate GFR:

$\mathrm{GFR} = K \times L/S_{\mathrm{Cr}}$ GFR=K×L/SCr

where GFR is expressed in milliliters per minute per 1.73 m^2 of BSA, *K* is the age-specific constant of proportionality (see below), *L* is the child's length in centimeters, and S_{Cr} is the serum creatinine concentration in milligrams per deciliter. Alternatively, for serum creatinine concentration expressed in µmol/L, the equation becomes: GFR = $K \times L \times 88.4/S_{cr}$. Conversion of GFR to units of mL/s/m^2 requires multiplication of GFR expressed in milliliters per minute per 1.73 m^2 by 0.00963.

Age	*K*
<1 year of age, low-birth-weight infant	0.33
<1 year of age, full-term infant	0.45
2- to 12-year-old child	0.55
13- to 21-year-old female	0.55
13- to 21-year-old male	0.70

Studies comparing the Schwartz-predicted GFR versus measured GFR noted that the Schwartz formula overestimated GFR in patients with decreasing GFR. The formula may not provide an accurate estimation of GFR in patients with rapidly changing serum creatinine concentrations, as seen in the critical care setting; in infants younger than 1 week; and in patients with obesity, malnutrition, or muscle wasting. Factors that interfere with serum creatinine measurement also may cause errors in estimation of GFR.

Changes in laboratory methods for measuring serum creatinine concentrations have led to the development of an updated equation to estimate GFR in children with impaired kidney function. The use of the old Schwartz equation with a serum creatinine concentration determined using current laboratory methods leads to an overestimation of GFR by approximately 10% to 20%.[48] GFR in 349 children enrolled in the Chronic Kidney Disease in Children Study, aged 1 to 16 years, was assessed using plasma iohexol clearance.[49] The updated formula derived from changes in laboratory methods for serum creatinine measurement is as follows:

$$\begin{aligned}\mathrm{eGFR}\left(\mathrm{mL/min/1.73m^2}\right) &= 39.1 \times \left(\mathrm{height}\left[\mathrm{m}\right]/S_{\mathrm{Cr}}[\mathrm{mg/dL}]\right)^{0.516}\\ &\times (1.8/\mathrm{cystatin\ C}[\mathrm{mg/L}])^{0.294}\\ &\times (30/\mathrm{BUN}[\mathrm{mg/dL}])^{0.169}\\ &\times (1.099)^{\mathrm{if\ male}} \times (\mathrm{height}[\mathrm{m}]/1.4)^{0.188}\end{aligned}$$

eGFR(mL/min/1.73m2)=39.1×(height[m]/SCr[mg/dL])0.516×(1.8/cystatin C[mg/L])0.294×(30/BUN[mg/dL])0.169×(1.099)if male×(height[m]/1.4)0.188

A simplified prediction equation (frequently referred as Bedside Schwartz equation) was also proposed:[50,51]

$$\mathrm{eGFR}\left(\mathrm{mL/min/1.73m^2}\right) = 0.413\left(\mathrm{height}\left[\mathrm{cm}\right]/S_{\mathrm{Cr}}\right)$$

eGFR(mL/min/1.73m2)=0.413(height[cm]/SCr)

The updated formulas do not provide an accurate estimation of GFR in patients with normal kidney function or patients with advanced kidney disease because these populations are outside the range of those enrolled in the Chronic Kidney Disease in Children Study. To use these equations, S_{Cr} expressed in µmol/L must first be divided by 88.4 to obtain conventional units of mg/dL, and blood urea nitrogen expressed in mmol/L must be divided by 0.357 to obtain conventional units of mg/dL. Conversion of GFR to units of mL/s/m^2 requires multiplication of GFR expressed in mL/min/1.73 m^2 by 0.00963. In addition, the estimated GFR values may be lower than actual for infants and adolescents and higher for low birth weight infants less than 1 year.

Serum drug concentrations should be monitored for drugs with narrow therapeutic indices and eliminated largely by the kidneys (eg, aminoglycosides and vancomycin) to optimize therapy in pediatric patients with impaired kidney function. For drugs with wide therapeutic ranges (eg, penicillins and cephalosporins), dosage adjustment may be necessary only in patients with moderately to severely impaired kidney function.

Cystic Fibrosis

Drug therapy in pediatric patients with cystic fibrosis has been reviewed.[52] For unknown reasons, these patients require increased doses of certain drugs. Studies have reported higher clearance of drugs, such as gentamicin, tobramycin, netilmicin, amikacin, dicloxacillin, cloxacillin, azlocillin, piperacillin, and theophylline, in patients with cystic fibrosis compared with patients without the disease. The apparent volume of distribution of certain drugs also may be altered in cystic fibrosis.[52] The severity of the illness may influence the change in dosage requirements, but this is not certain. Chapter 47 reviews these changes in detail.

Obesity

① Children and adolescents are classified as being overweight or obese according to CDC age- and gender-specific percentiles for body mass index (BMI). The CDC and the AAP categorize overweight children as having a BMI percentile greater than 85th to less than 95th and obese children as having a BMI percentile of or greater than the 95th percentile.[53]

Obesity rates have been steadily increasing from 1999 to 2000 through 2017 to 2018 for children and adolescents aged 2 to 19 years. The obesity rate in 2017 to 2018 was 19.3% with an obesity prevalence of 13.4% among children 2 to 5 years of age, 20.3% for children 6 to 11 years of age and 21.2% among 12 to 19 years of age.[54–56] Rate of BMI increase in children 2 to 19 years of age nearly doubled during the Coronavirus disease pandemic compared to the prepandemic period. Obesity prevalence of 19.3% in persons 2 to 19 years of age prepandemic increased to 22.4% during the pandemic. The impact from stay-at-home orders and school closures resulted in a decline in physical activity and weight gain.[57,58] Interventions that promote healthy behavior such as weight management programs, food assistance that facilitates healthy eating, and exercise programs to increase physical activity are needed.

Obese children are at risk for metabolic complications and the development of comorbid conditions, including high blood pressure, high cholesterol, type 2 diabetes mellitus, nonalcoholic fatty liver disease, polycystic ovary disorder, cholecystitis, gastroesophageal reflux disease, and obstructive sleep apnea.[59] During a 1999 to 2008 study period, 49% of overweight and 61% of obese adolescents had one or more cardiovascular risk factors, which included prehypertension or hypertension, low high-density lipoprotein cholesterol and high low-density lipoprotein cholesterol, and elevated fasting glucose concentration. Obese children are more likely to have early-onset puberty.[60]

A 50% increased recurrence of acute lymphoblastic leukemia in obese children older than 10 years of age compared with lean children with cancer has also been reported. BMI > 30 kg/m^2 was associated with worse event-free survival, disease-free survival, and overall survival.[61,62] Studies show that obesity can directly impair the antileukemia efficacy of first-line chemotherapeutic agents and accelerate leukemia progression.[63] Adipocytes attract acute lymphoblastic leukemia (ALL) cells to migrate closer to fat cells which absorb chemotherapy decreasing its exposure to the cancer cells. Adipocytes secrete asparagine, glutamine, and fatty acids that contribute to the survival of leukemia cells lessening the probability of the patient's survival.[64,65] In addition, higher rates of life-threatening or fatal complications to chemotherapy have been reported with obese children and adolescents than normal weight children. A retrospective study compared safety and efficacy between obese and normal-weight children who received methotrexate, teniposide, etoposide, and cytarabine for the treatment of acute lymphoblastic leukemia. No significant difference existed on the basis of BMI in the rate of complete remission, overall survival, incidence of relapse, and frequency of toxicity. Chemotherapy doses were based on BSA calculated using total body weight for all children. Findings suggest that the doses of cytarabine, etoposide, teniposide, and methotrexate in obese children should be based on BSA calculated using total body weight.[66] These findings are consistent with the recommendations for appropriate chemotherapy dosing in adult obese patients, which advise use of the patient's actual body weight when calculating the dose and not limiting the dose or using an adjusted ideal body weight unless there is an established dosing limit. Limiting the dose in obese patients may lead to poorer outcomes and undertreatment.[67] Obesity is also associated with cancer mortality. Obesity is responsible for more than 90,000 cancer deaths/year in the United States.[68] However, obese patients who achieved normal or overweight status for greater than 50% of the treatment duration had outcomes comparable to those in normal or overweight individuals. Non-pharmacologic interventions of improving diet and exercise may increase chemotherapy efficacy and disease response by increasing circulatory adiponectin and reducing insulin resistance, decreasing fat gain in overweight/obese patients and reducing minimal residual disease for patients with acute lymphoblastic leukemia.[69,70]

Obese children have a higher proportion of body fat, which generally results in a higher volume of distribution (V_D) for lipophilic drugs and a lower V_D for hydrophilic medications compared with normal-weight children. Obese children have higher total body water, lower percent lean mass, increased organ mass, and greater cardiac output, GFR, and serum creatinine concentrations than normal-weight children.[71] Many antibiotics are hydrophilic medications that distribute to extracellular water. Adipose tissue contains approximately 30% water, meaning that many antibiotics will not distribute adequately in obese patients.

Correction factors have been used to adjust drug dosing in obese children. A correction factor is multiplied by the actual body weight less the ideal body weight, and this value is added to the ideal body weight. The drug dose is then determined based on this weight. Correction factors are 0.3 for β-lactams, 0.45 for ciprofloxacin, and 0.4 for aminoglycosides.

The Pediatric Pharmacy Association supports the following in determining initial empiric medication doses for overweight/obese children:

- Weight-based dosing should be used in patients <18 years of age who are <40 kg
- Children ≥40 kg: Use weight-based dosing unless the patient's dose exceeds the recommended maximum adult dose for the specific indication
- When possible, plasma drug concentration monitoring should be used to adjust dosing; few studies have been conducted to establish effective drug dosing information for obese children.[72,73]

Vancomycin distributes into total body water and other tissues and is eliminated primarily by glomerular filtration. Vancomycin is empirically dosed using actual body weight in overweight and obese children; the dose is not capped at the usual maximum adult dose. Every-8-hour dosing is used initially; the frequency can be increased to every-6-hour dosing for complicated infections using serum concentration monitoring to individualize the dose.[74]

Obesity may affect warfarin dosage requirements in pediatric patients. Obese pediatric patients had an increased time to reach therapeutic INR values with the use of institutional dosing guidelines.[75] Additional studies are needed to determine warfarin dosage requirements in obese versus nonobese pediatric patients.

Pharmacokinetic studies of anesthetic agents in obese children have not been conducted to characterize distribution, adipose tissue accumulation, and elimination. One study showed that obese children lose consciousness at a significantly lower propofol dose than patients with a healthy weight. Whereas an IV propofol dose of 2 mg/kg was effective in 95% of children with BMIs above the 95th percentile, those with lower BMIs each required a higher dose of 3.2 mg/kg.[76]

Specific studies are needed to identify the effects of childhood obesity on pharmacokinetics, pharmacodynamics, and efficacy of medications so that optimal drug dosing can be determined for this population.

Other Conditions

Although specific dosage guidelines are not available, pediatric patients with gastrointestinal disease (eg, celiac disease, gastroenteritis, and severe malabsorption) may require dosage adjustments.[43] Hypoxemia also has been shown to decrease the elimination of amikacin in low-birth-weight infants.[77] Critically ill adult and pediatric patients with severe head trauma require higher than normal doses of phenytoin in part because of increased intrinsic clearance.[78]

KEY ISSUES IN PEDIATRIC PHARMACOTHERAPY

Pain Management

7 For many years, the term *pain* could not be found in the index of any major pediatric medicine or pediatric surgical textbook.[79] The prevailing wisdom was that neonates did not experience pain because of their inadequately developed neuroendocrine systems and nerve pathways. During the last years of the 20th century, however, many research and clinical studies were performed in the areas of pain management and assessment of neonates, infants, children, and adolescents. Today, the results of these discoveries have been incorporated into clinical practice, making effective pain therapy a standard of pediatric care which must be adequately addressed as with the practice in adults.[80]

The basic mechanisms of pain perception in infants and children are similar to those of adults, except that pain impulse transmission in neonates occurs primarily along slow-conducting, unmyelinated C fibers rather than along myelinated A-delta fibers. In addition, pain signal transmission in the spinal cord is less precise, and descending inhibitory neurotransmitters are lacking. As a result, neonates and young infants may perceive pain more intensely and be more sensitive to pain than older children or adults.[81] It is now known that previous pain experience leads to long-term consequences such as alterations in response to a subsequent painful event.[82] Taddio et al.[83,84] reported that boys circumcised with the topical anesthetic eutectic mixture of local anesthetics (EMLA) had lower pain responses to subsequent immunizations than those who were circumcised without topical anesthesia. An inadequately treated initial painful procedure may decrease the effect of adequate analgesia in subsequent procedures as a result of altered pain response patterns.

Children consistently report that needles and shots are what they fear most. However, with the current immunization schedule that recommends 14 to 33 injections before adolescence, interventions to decrease injection pain need to be performed (Table e20-1).[85–90]

TABLE e20-1

Techniques for Minimizing Pain Caused by Injection

Pharmacologic Methods	
EMLA[85]	*Advantages:* Penetrates the skin to provide anesthesia to a depth of 5 mm; effective in decreasing the pain of IM and subcutaneous injections, venipuncture, IV cannulation, lumbar puncture, circumcision, skin-graft harvesting, and laser dermal therapy; safe and effective in newborns >37 weeks' gestation. *Disadvantages:* Requires 1 hour before onset of adequate anesthesia, has a vasoconstrictive effect that may make starting IV catheters difficult, and may induce methemoglobinemia
J-tip with buffered lidocaine[86,91]	*Advantages:* Provides dermal anesthesia to a depth of 5-8 mm within 1-3 minutes; effective in decreasing the pain of IV cannulation *Disadvantage:* Makes a popping noise; this can scare a patient who is not properly prepared

Vapocoolant sprays (ethyl chloride or dichlorodifluoromethane)[87]	*Advantages:* Vapocoolant is sprayed directly onto the skin or applied to a cotton ball that is held on the area to be anesthetized; provides local anesthesia within 15 seconds; effective in reducing injection pain in children 4–6 years of age *Disadvantages:* Brief duration of action, so procedure should be completed in 1 or 2 minutes; may not be effective in reducing injection pain in infants aged 2-6 months
Local anesthetic (lidocaine)[88]	*Advantage:* Reduces the pain of subsequent needle insertion *Disadvantage:* Local anesthetic injection itself is associated with pain and burning sensation
Pacifier with sucrose[89]	*For preterm neonates:* 0.1-0.4 mL of a 12%-24% sucrose solution (place on pacifier or the tongue 2 minutes before procedure); *for term neonates:* 1-2 mL of a 12%-24% sucrose solution (place on pacifier or the tongue 2 minutes before procedure) *Advantage:* Noninvasive method to reduce pain associated with needle insertion in infants *Disadvantage:* Sucrose solution's effect in reducing pain gradually decreases over time; loses efficacy by 4-6 months of age
Other Techniques	
Site selection[90]	*For children older than 18 months:* Use of the deltoid muscle for IM injections is associated with less pain than injections administered in the thigh; *for children older than 3 years*: Use of the ventrogluteal area for injection is associated with less pain than the anterior thigh or dorsogluteal area
Z-tract technique	Z-tract IM injection technique is less painful (pull skin taut at the injection site, give injection, and then release the skin); use a higher-gauge needle when the injectable solution is not viscous
Behavioral	Use of distraction methods (eg, blowing bubbles, providing music by headphones, relaxation, imagery, self-hypnosis, or having parents present for the procedure) can be helpful
Virtual Reality[92]	Pediatric patients undergoing PIVC placement who received a Virtual Reality intervention experienced significantly less anxiety and pain compared to patients receiving standard care (simple distraction techniques [eg, music, coloring, singing, and talking] and the application of numbing cream)

EMLA, eutectic mixture of lidocaine and prilocaine; IM, intramuscular.

Pharmacologic pain management for medical conditions and surgical and postoperative events has progressed considerably over the past decade with the use of continuous opioid infusions, patient-controlled analgesia, epidural anesthesia, peripheral nerve blockade, local anesthetics, liposomal bupivacaine via local infiltration for postsurgical local analgesia, nonsteroidal antiinflammatory drugs, different routes for traditional agents (ie, transmucosal and transdermal), and nonopioid adjuvant drugs (Table e20-2).[93–98] Opioids are frequently prescribed for children after surgery but evidence-based guidelines for opioid prescribing in children to provide optimal postoperative pain management are lacking. Best practice concepts like standardizing opioid dosing strategies that are age and procedure specific, and use of multimodal and opioid-sparing regimens have been difficult to implement due to the challenging nature of managing pain, as well as balancing the prevention of drug diversion and opioid abuse. Opioid-prescribing guidelines for safer postoperative pain management in children and adolescents have been developed to minimize risks associated with opioid use and maximize nonopioid regimens.[99] Pain management techniques, education, research, developmentally appropriate pain assessment scales, implementation of opioid and pain stewardship programs and increasing awareness of pain management options have helped to improve the quality of life in children.

TABLE e20-2

Opioid Administration for Acute and Severe Pain

Intermittent IV or PO bolus administration (not as needed)	In 2018, the FDA announced limiting use of prescription opioid cough and cold medications containing codeine or hydrocodone in children <18 years old. Weak opioids (eg, codeine, hydrocodone, and oxycodone) often are combined with acetaminophen or an NSAID for moderate pain. With dose escalation of combination oral products, be aware that the dose does not exceed recommended daily amounts for acetaminophen or ibuprofen. 1%-7% of the general population and up to 28% of some ethnic groups have a genetic variation in the enzyme cytochrome P450 2D6 that causes codeine to be converted to morphine faster and more completely. In 2012, the FDA issued a Drug Safety Communication stating that codeine use in certain children after tonsillectomy or adenoidectomy for obstructive sleep apnea syndrome led to deaths and life-threatening respiratory depression. Consider alternative analgesics for children undergoing tonsillectomy or adenoidectomy. If codeine or codeine-containing products are prescribed, then use the lowest effective dose for the shortest period of time on an as-needed basis.[100] IV administration of codeine has been associated with allergic reactions related to histamine release. Parenteral administration of codeine is not recommended. Intermittent opioid administration is associated with wide fluctuation between peak and trough concentrations, so the patient may alternate between peak blood concentrations associated with untoward effects and trough concentrations associated with inadequate pain relief when being treated for severe pain.
	Oxycodone and morphine are available in a sustained-release formulation for use with chronic pain (not acute pain). The tablet must be swallowed whole and cannot be administered to patients through gastric tubes.
IV continuous infusion[93,94]	Loading dose is administered to rapidly achieve a therapeutic blood concentration and pain relief (ie, morphine loading dose of 0.05-0.15 mg/kg in children; 0.1 mg/kg infused over 90 minutes in neonates). Loading dose is followed by a maintenance continuous infusion. Doses that are considered safe in children can cause respiratory depression and seizures in neonates because of decreased clearance, immature blood–brain barrier at birth that is more permeable to morphine, and an increased unbound fraction of morphine that increases CNS effects of the drug.
PCA[95]	Gives patient some control over his or her pain therapy. PCA allows the patient to self-administer small opioid doses. The PCA-Plus (Abbott, Chicago, IL) pump allows the patient to receive a continuous infusion together with a set number of self-administered doses per hour. PCA helps to eliminate wide peak and trough fluctuations so that blood concentrations remain in a therapeutic range. Children as young as 5 or 6 years of age can master the use of PCA.
Epidural and intrathecal analgesia[96]	Effective in the management of severe postoperative, chronic, or cancer pain. Spinal opioids can be administered by a single bolus injection into the epidural or subarachnoid space or by continuous infusion via an indwelling catheter. Dosage requirement by these routes is significantly less than with IV administration. Morphine, hydromorphone, fentanyl, and sufentanil are effective when administered intrathecally. Bupivacaine is the most commonly used local anesthetic in continuous epidural infusions. Fentanyl, morphine, or hydromorphone usually is combined with bupivacaine for epidural infusions. Transdermal administration. Fentanyl and buprenorphine are available as a transdermal formulation. Multiple patches of an agent may be applied for patients who require higher doses. Disadvantage of transdermal administration is the requirement for an alternative short-acting opioid for break-through pain.
Transmucosal administration	Fentanyl lozenge is absorbed transmucosally. It is useful for providing analgesia during painful procedures. Advantages include rapid onset of action (within 15 minutes), short duration of action (60-90 minutes), and painless administration because no injection is needed. Common side effects are vomiting and mild to moderate oxygen desaturation. Doses of 10-15 μg/kg provide blood concentrations equivalent to 3-5 μg/kg IV.

FDA, Food and Drug Administration; IM, intramuscular; NSAID, nonsteroidal antiinflammatory drug; PO, by mouth; PCA, patient-controlled analgesia.

Drug Administration

8 Drugs often are given by the IV route to seriously ill patients. Syringe pumps are widely used for administration of IV drugs. Important steps in successfully administering IV drugs include selecting the drug, calculating the dose, preparing the infusion, programming the infusion pump, and delivering the infusion. Use of "smart" pumps is preferred because they can recognize syringes and have drug libraries and dose limits as safety features. The pumps should be accurate, precise, and easy to use; accept syringes and administration sets from various manufacturers; offer extensive delivery mode combinations, including milliliters per hour, body weight, mass, volume over time, custom dilution and intermittent, loading dose, bolus dose, standby, and volume limit; have wide-ranging flow rates and rate to keep vein open; and have an adequate internal battery capacity.

No single infusion system is ideal for delivery of all drugs in all institutions for all patients. Each facility must be cognizant of problems of drug delivery and develop specific guidelines for IV infusions. At each institution, specific guidelines should be provided for administration of each drug. These guidelines take into account various infusion rates and provide consistency of delivery with each dose. As long as the time for actual delivery is known, times to obtain blood samples for measurement of drug concentration can be adjusted accordingly to generate meaningful data.

Alteration of Dosage Forms

9 Many drugs used in pediatric patients are not available in suitable dosage forms. This necessitates dilution of high concentrations of drugs intended for adult patients. Examples of these drugs include atropine, diazepam, digoxin, fentanyl, epinephrine, hydralazine, insulin, morphine, phenobarbital, and phenytoin. Volumes ranging from 0.01 to 0.1 mL must be measured to dispense these drugs for use in infants. This obviously can be associated with large errors in measurements, and such errors have caused intoxication with digoxin[101] and morphine[102] in infants. One solution to this problem is to dilute these concentrated products, but such alterations can influence the stability or compatibility of these drugs. Because of limited data, pharmacists justifiably may be reluctant to alter dosage forms of certain drugs.

Selection of the appropriate vehicle to dilute the adult dosage forms for use in pediatric patients can be difficult. Phenobarbital sodium contains propylene glycol in the original product to improve drug stability. As propylene glycol can cause hyperosmolality in infants,[37] further addition of this vehicle may not be wise. Because of limited access to IV sites in pediatric patients, drugs must be administered through the same site; however, data on drug compatibilities often are missing. Newborn infants often require aminoglycosides for presumed or proven sepsis and calcium gluconate for correction of hypocalcemia or calcium supplementation. Tobramycin and calcium gluconate were compatible, at least during a 1-hour administration at the same site.[102]

Administration of oral drugs continues to challenge parents and nurses. Alteration of these drugs by crushing or mixing, refusal of patients to accept the medication, and loss of drug during administration are some factors that can affect pediatric therapy. A common practice is to mix medications in applesauce, syrup, ice cream, or other vehicles just before administration to make the drugs palatable. In 2015, the FDA has approved levetiracetam (Spritam) that uses 3D printing technology, paving the way for potential customization of drugs to meet the needs of pediatric patients. It uses a delivery system that creates premeasured doses which disintegrate in the mouth with a small volume of liquid.

A number of extemporaneous formulations for oral, IV, and rectal administration are included in a compilation of products for use in pediatric patients.[103] However, a specific reference on the stability of many drug formulations is lacking and emphasizes the need for continued research in this area.

Drug administration into the middle ear, nose, or eye of a child requires special attention. Certain drugs (eg, sodium valproate and morphine) can be administered rectally to infants who have limited access for IV drug administration or if oral drug administration cannot be accomplished.

Flexibility of Dosage Forms

Factors including age, health condition, indication for use, ability to take the medication, availability of various dosage forms, and patient or caregiver preference should be considered in selecting an optimal dosage form for patients. As example, oral medications may be administered in many forms including drops, liquid, tablets (eg, regular, chewable, disintegrating or film), granules and capsules. Some medications are available in multiple flavors including cherry, strawberry, grape, banana, bubble gum and orange.

Transdermal drug delivery can be used in pediatric patients (a) to avoid problems of drug absorption from the oral route and complications from the IV route and (b) to maximize duration of effect and minimize adverse effects of drugs. As discussed earlier in this chapter, methylphenidate (Daytrana) now is available as a transdermal patch for children with ADHD. However, the commercially available transdermal dosage forms (eg, clonidine and scopolamine) are not intended for pediatric patients; these would deliver doses much higher than needed for infants and children.

Medication Adherence

The issue of medication adherence is more complex in pediatric patients than in adults. Caregivers of young patients must appreciate the importance of understanding and following the prescribing information.

In one study, medication adherence was considered to be a problem in nearly 60% of adolescents (age 12-15 years) with asthma. Approximately 40% of patients had severe denial regarding their asthma and its severity. Nearly 80% of patients had preventable asthma exacerbations.[104]

Among the factors that can negatively affect adherence are poor communication between the physician and patient or parent, insufficient prescribing information, lack of understanding about the severity of illness by the patient or parent, lack of interest (eg, among adolescents), fear of side effects, failure of the patient or parent to remember to administer the drugs, inconvenient dosage forms or dosing schedules involving administration of three or more doses daily, and unpalatability of drug products.[105] Studies in pediatric volunteers have compared the palatability of antibiotics,[106] and the data may have important implications for adherence in children.

Dose Requirements

Medication doses often are based on the body weight of neonates, infants, and children (eg, milligrams per kilogram of body weight per day to be given in one or more portions daily). However, certain drugs, including antineoplastic agents, may be given based on BSA (eg, milligrams per square meter in one or more doses daily). In either case, the total amount of weight- or surface area-based individual or daily dose in a pediatric patient, especially an adolescent, should generally not exceed the amount of drug indicated in an adult patient.

An additional challenge in managing pediatric drug therapy is understanding the effects of obesity on a population that relies on weight-based dosing. As mentioned earlier, the number of children who are overweight or obese has increased markedly over the past four decades.[54,55] Using ideal body weight versus total body weight to calculate a weight-based dose or to determine BSA can result in a large variance in obese patients. Additional pharmacokinetic studies are needed to study the effects of obesity on drug distribution, protein binding, and clearance and to identify whether dosing should be adjusted according to total body weight or ideal body weight to achieve consistent drug exposure for individual drugs.[107,108] Generally, the highest drug dose recommended for a child is the maximum dose approved for adults. However, determining the highest dose of certain drugs for use in children without a known maximum dose for adults (eg, IV immunoglobulin, infliximab, rituximab, and liposomal amphotericin B [AmBisome]) can be difficult.

It should be realized that estimation of dose requirements based on scaling with body weight or surface area assumes linear growth and maturation affecting pharmacokinetics and pharmacodynamics. This assumption may not be valid across all age groups ranging from premature newborns to 18 years old. Thus, optimal dosage requirements should be determined from the findings of pharmacokinetics, pharmacodynamics, efficacy, and safety studies in specific pediatric cohorts. There is also a need to identify appropriate biomarkers that may reflect desired clinical endpoints specifically in the pediatric population, since inconsistent findings may be observed in pediatric patients versus adults. For example, unlike systolic blood pressure in adults with hypertension, diastolic blood pressure may be a preferred age-appropriate pharmacodynamic/response biomarker in pediatric patients with hypertension.[109]

Drug Interactions

Drug interaction studies in pediatric age groups generally are lacking. The data often are extrapolated from studies in adult populations. Special attention should be given to adolescents, who may concurrently use alcohol, recreational or illicit drugs, or other prescription or nonprescription medications without the knowledge of the primary healthcare provider, who must attempt to determine their use to avoid drug interactions.

Complementary and Alternative Therapy

In a study of patients between 3 weeks and 18 years (mean, 5.3 years) of age, 45% of caregivers gave a complementary or alternative treatment to the children; 27% had given three or more products in the past year. The most commonly used products were aloe plant or juice (44% of those reporting use of herbal therapies), Echinacea (33%), and sweet oil (25%). The most dangerous combination was ephedra (which was withdrawn from the US market in 2004) with albuterol given to adolescents with asthma. Most caregivers did not recognize potential adverse effects or drug interactions associated with herbs. Friends or relatives were the main sources of information for 80% of caregivers.[110]

Little is known about the efficacy of herbal products in infants, children, and adolescents. Healthcare professionals must ask caregivers specifically about the use of complementary and alternative treatments to minimize the adverse effects and costs associated with ineffective therapies.

Marijuana has been used in pediatric patients with life-limiting or severely debilitating conditions (eg, cancer and epilepsy) when other treatments were ineffective. In 2018, cannabidiol (Epidiolex®) was the first FDA-approved cannabis-based drug marketed to treat two forms of epilepsy, Lennox-Gastaut syndrome and Dravet syndrome in patients ≥ 2 years of age. It was classified as a Schedule V prescription drug.[111,112] A 2015 policy statement of AAP cited several studies documenting the adverse effects of marijuana in adolescents.[113] These have included impaired learning due to decreased short-term memory, attention span and problem solving ability; risks with motor vehicle driving associated with changes in motor control, coordination, judgment, and tracking ability; brain development; and drug dependence or addiction which may develop later in adulthood. AAP recommended that research and development under FDA regulations be continued to demonstrate short-term and long-term effectiveness and safety of cannabidiol among children and adolescents.

Breakthrough Therapies

Gene therapy is being used to provide better outcomes and potential curative therapies at the patient level for diseases not previously treatable. Use of new gene correction technologies such as gene editing and gene silencing, replacing faulty genes, as well as using viruses to insert genes into blood-forming stem cells are part of the strategy of delivering breakthrough therapies.[99] Survival rate for pediatric ALL is ~80% to 90% with standard chemotherapy. Relapsed ALL is the leading cause of cancer deaths in children. Tisagenlecleucel is a chimeric antigen receptor T-cell (CAR-T) therapy that simultaneously serves as cell therapy, gene therapy and immunotherapy. The drug was approved by the FDA for patients 3 to 25 years of age with B-cell precursor ALL that is refractory to treatment or for patients who experience relapse. Up to 75% of patients with refractory disease are alive at 1-year after CAR-T therapy with more than 60% cured.[114–116]

The FDA approved voretigene neparovec-rzyl, the first gene therapy for the treatment of patients ≥12 months of age with confirmed biallelic RPE65 mutation-associated retinal dystrophy, a disease caused by mutation in a specific gene. Voretigene neparovec-rzyl works by sending a normal copy of the RPE65 gene directly to retinal cells, which can then produce the enzyme essential for normal vision.[117]

Spinal muscular atrophy (SMA) is caused by mutations in the survival motor neuron gene which results in loss of alpha motor neurons in the spinal cord. SMA (type 1) is the leading cause of death from genetic disease in infants who ultimately develop respiratory failure. Median survival is 6 to 8 months in treatment-naïve patients with SMA type 1. Onasemnogene abeparvovec, a recombinant adeno-associated virus serotype 9 vector gene replacement therapy, delivers a functional copy of the human SMN gene that crosses the blood–brain barrier after a single intravenous infusion. All patients in the therapeutic-dose cohort of the START phase 1 trial were alive without the need of permanent ventilation at 24 months of age. A long-term ongoing follow-up study at the therapeutic-dose showed a durable response in patients which was maintained up to 6.2 years after dosing.[118]

Medication Safety

⑩ The Institute of Medicine reported that between 44,000 and 98,000 Americans each year die as a result of medical errors in hospitals.[119] According to this report, the vast majority of medical errors that cause harm to patients are preventable. Healthcare professionals have a responsibility for creating a safe medication environment and reducing risk to a vulnerable pediatric population.

Pediatric medication errors commonly occur at the medication-ordering step because of the multiple calculations required for weight-based dosing and the adjustments needed for providing therapy to the developing pediatric patient.[120–122] The United States Pharmacopeia (USP) Center for the Advancement of Patient Safety states that risk to patients when performing repeated calculations involving multiple steps can be minimized using computer-based algorithms.[123] Because the medication-preparation step is also a high-hazard point owing to the need for dilution or manipulation of commercially available products only available in adult doses, the USP recommends that compounded pediatric medications be prepared and labeled in the pharmacy and verified by a pharmacist. In 2006 and 2007, there were several reports of heparin-dispensing errors to neonatal patients caused by different concentrations of the same medication used to service the needs of neonates and adults (neonatal and adult product mix-up).[124–128] In 2008, The Joint Commission issued an alert on preventing errors related to commonly used anticoagulants.[129] Among drug administration-related errors, wrong dose, wrong technique, and wrong drug are the three most common errors and may be related to an inability to access pediatric drug information. In 2001, the Agency for Healthcare Research and Quality published an evidence-based assessment of patient safety practices that prevent or reduce medication errors.[124] Risk-reduction strategies include placing a clinical pharmacist on pediatric wards in hospitals, simplifying the medication-use system, ordering standardized concentrations and doses, implementing computerized provider order entry systems with clinical decision support and dosing alerts, dispensing pharmacy-prepared or ready-to-administer doses, standardizing infusion equipment, using smart infusion pumps, using bar-coded medications and bar-coding systems that check the medication at the point of care, and implementing computerized adverse event detection systems.[122,124–126,130] Identifying and understanding the high-hazard areas or points of failure in the medication-use process will help in designing strategies that prevent problems before they arise (see Chapter e4).

Pharmacogenomics and Medication Prescribing

Since most currently used drugs are prescribed as “one size fits all” without knowledge and/or application of adequate pharmacogenomic data from pediatric patients, this approach can potentially lead to subtherapeutic response or toxicity, in part due to the presence of genomic variants in certain patients (see Chapter e7). Pharmacogenomic research is needed to understand the influence of genes on drug response to determine effective and safe medications and doses, specific to an individual patient’s genotype. Although most of the information is derived from studies done in adults, the Food and Drug Administration updates the “Table of Pharmacogenomic Biomarkers in Drug Labeling” and “Table of Pharmacogenetic Associations” to consider an increasing role of pharmacogenomics in drug prescribing.[131,132] Of the 308 drug-gene pairs identified, 36% were associated with a biomarker defined drug indication, 33% with polymorphic drug metabolism, and 28% with susceptibility to adverse drug reactions. This type of information may guide prescribing decisions to improve the use of medications in pediatric patients.[133]

CONCLUSIONS

Although tremendous progress has been made in the area of pediatric pharmacotherapy, many questions remain unanswered. The pharmacokinetics of many important drugs have been elucidated, but their pharmacodynamics have not been explored fully. Similarly, the effect of disease states and patient characteristics, such as genetic status, has not been studied for most drugs. The effect of these factors on the development of CYP isozymes (eg, CYP3A4, CYP2D6, CYP1A2, CYP2C9, and CYP2C19), other enzymes, and P-glycoprotein needs to be studied (see Chapters e6 and e7). Targeted precision therapy matched to molecular alterations identified by tumor profiling offers possibility for improved treatment in pediatric cancer. Similarly, comparative efficacy and safety data for many therapies are unavailable. Studies on the influence of pharmacogenomics on drug therapy to achieve optimal clinical and economic outcomes and quality of life in pediatric patients are needed.

The development of new drugs has contributed to improved patient care. Food and Drug Administration regulations can require the industry to conduct studies and seek labeling of important drugs for use in pediatric patients. As an incentive, a 6-month patent extension and waiver of supplemental new drug application fee are offered to the industry. This should encourage the industry to develop and market more drugs for the pediatric population. However, greater emphasis also should be placed on disease prevention. Millions of children die because of preventable diseases, particularly in developing countries of the world. Administration of vaccines and control of diarrhea alone could save millions of these lives annually. However, many countries may lack resources for vaccinations. The infant mortality rate in the United States is nearly twice as high among Blacks as Whites. Improved prenatal care; educational programs; and avoidance of harmful substances including alcohol, smoking, and drugs during pregnancy may decrease mortality rates as well as morbidity from illnesses, including acquired immunodeficiency syndrome.

Finally, efforts should be made to offer evidence-based pharmacotherapy. This often is difficult in pediatric populations when the drugs must be used outside the guidelines and indications approved by the FDA. Institutions should develop guidelines for the use of drugs in specific diseases and for the use of high-risk and high-cost drugs.

Although much needs to be learned about the optimization of therapy, it is encouraging to witness the continued growth and application of knowledge in this area that has improved the quality of life and survival from pharmacotherapy in pediatric patients.

SELF-ASSESSMENT QUESTIONS

1. Newborn infants born prior to which of the following gestational ages are considered premature infants?

   A. 37 weeks

   B. 39 weeks

   C. 40 weeks

   D. 42 weeks

2. Kernicterus associated with sulfonamide in infants develops because of:

   A. Displacement of albumin by bilirubin

   B. Displacement of bilirubin from albumin by a sulfonamide

   C. Decreased metabolism of bilirubin

   D. Increased concentration of albumin

3. Compared with older patients, premature infants may have:

   A. Increased absorption of oral doses of weak acids such as phenobarbital

   B. Decreased absorption of intramuscular doses of all drugs

   C. Increased percutaneous absorption of drugs

   D. Rectal route should never be used in infants

4. Based on extracellular fluid (ECF) volume, which of the following populations is expected to have the largest apparent volume of distribution per kilogram of body weight for a drug largely distributed in ECF?

   A. Premature infants

   B. Children

   C. Adolescents

   D. Adults

5. Premature infants may need higher plasma concentrations of morphine for pain control than older patients because they have:

   A. Decreased metabolism to the more active metabolite

   B. Lower sensitivity to pain

   C. Increased urinary excretion of morphine

   D. Decreased absorption of morphine

6. Which of the following age groups generally requires the highest daily dose of theophylline per kilogram of body weight?

   A. 1-month-old infant

   B. 6-month-old infant

   C. 5-year-old child

   D. 15-year-old adolescent

7. Which of the following statements is true about adverse effects of drugs in pediatric patients?

   A. Tetracyclines are indicated for patients younger than 8 years of age.

   B. Benzyl alcohol is safe in premature infants.

   C. Promethazine is safe for use in infants.

   D. Aminoglycosides can be used safely in children at recommended doses with monitoring.

8. The FDA does not recommend the use of OTC cough and cold products in children younger than:

   A. 1 year

   B. 2 years

   C. 3 years

   D. 4 years

9. Ciprofloxacin has been approved by the FDA for use in children with:

   A. Community acquired Pneumonia

   B. Acute otitis media

   C. Complicated urinary tract infection

   D. Uncomplicated lower urinary tract infection

10. Knowledge of pharmacogenomics can be used to determine:

   A. Biomarker defined drug indication

   B. Polymorphic drug metabolism

   C. Susceptibility to adverse drug reactions

   D. All of the above

11. The daily dosage requirement of aminoglycosides in children with cystic fibrosis (CF) versus in those without CF is often:

    A. Increased

    B. Decreased

    C. Similar

    D. Unknown

12. The CDC and the American Academy of Pediatrics have categorized obese children as having a BMI percentile of:

    A. ≥99th

    B. ≥85th

    C. ≥95th

    D. None of the above

13. Chemotherapy dosing in pediatric obese patients should be based on BSA calculated by using:

    A. Lean body weight

    B. Actual body weight

    C. Ideal body weight

    D. Ideal body weight minus extracellular water weight

14. What percentage of adolescents with asthma may experience a problem with medication adherence?

    A. 10%

    B. 30%

    C. 60%

    D. 90%

15. Which of the following risk-reduction strategies may prevent and reduce medication errors to pediatric patients?

    A. Ordering standardized doses

    B. Dispensing pharmacy-prepared/ready-to-administer doses

    C. Implementing computerized physician order-entry system with dose range checking

    D. All the above strategies are correct

SELF-ASSESSMENT QUESTION-ANSWERS

1. **A.** Infants born before 37 weeks of gestational age are considered premature because of underdeveloped organ systems including lungs, liver and brain. Those born at or above 37 weeks of gestational age are unlikely to experience health problems due to underdevelopment.

2. **B.** Sulfonamide can displace bilirubin bound to albumin in the plasma in infants. The increased amount of unbound bilirubin can cross the blood brain barrier and lead to kernicterus characterized by encephalopathy.

3. **C.** Absorption of orally administered a weak acid may be decreased due to higher gastric pH. Absorption of drugs after intramuscular administration is difficult to predict. Percutaneous absorption is increased due to underdeveloped epidermal barrier. Rectal route has been used for administration of certain drugs.

4. **A.** The extracellular fluid volume (ECF) per kilogram of body weight is highest in premature infants compared to older patients. Thus, the apparent volume of distribution per kilogram of drugs largely distributed in ECF is largest in the premature infants versus full-term infants, children, adolescents and adults.

5. **A.** Premature infants may not be able to metabolize morphine to its more active metabolite 6-glucuronide due to underdeveloped liver function. This may explain the need for higher dose of morphine to achieve the desired effect.

6. **C.** The clearance of theophylline per kilogram of body weight is highest in children of age 1 to 9 years in comparison to infants and adolescents. Thus, a 5-year old would require a higher dose of theophylline compared to an infant or an adolescent.

7. **D.** Tetracyclines are not indicated in children younger than 8 years due to adverse effects including dental staining and defects in enamelization and bone growth. Benzyl alcohol is contraindicated in premature infants due to severe toxicities including metabolic acidosis, neurologic adverse effects, and death. Promethazine has been associated with respiratory depression in infants. Aminoglycosides have been used safely at recommended doses with appropriate monitoring of serum concentration and kidney function.

8. **B.** Cough and cold products have been associated serious toxicities with overdoses in young children. Further, their efficacy has been unproven. Thus, the FDA does not recommend the use of these medications for children younger than 2 years.

9. **C.** Ciprofloxacin is approved by the FDA for complicated urinary tract infections because the benefits may exceed risks of adverse effects. There are many safer and effective alternative antibiotics for uncomplicated urinary tract infections. Ciprofloxacin would not adequately cover the pathogens causing community acquired pneumonia and acute otitis media.

10. **D.** Pharmacogenomic studies can be instrumental in individualizing the prescribing and the use of a drug and dosage regimen for a specific patient affected by an illness. The data can also be used for prevention or management of adverse drug reactions.

11. **A.** The clearance of aminoglycosides is markedly increased in children with cystic fibrosis (CF) in comparison with those without CF. Thus, patients with CF would require a higher daily dose of an aminoglycoside than those without CF.

12. **C.** The CDC and the American Academy of Pediatrics have defined obesity as the BMI percentile of 95th or greater. Studies have linked obesity with an increased risk of metabolic complications and development of comorbidities including hypertension and type 2 diabetes.

13. **B.** Studies have shown that chemotherapy dosing in obese patients should be based on BSA calculated by using actual body weight as in adults. Use of ideal or lean body weight may lead to underdosing and poor health outcomes.

14. **C.** As many as 60% of adolescents with asthma may experience difficulties with adherence to medications to control this condition.

15. **D.** Medication errors can be prevented or reduced by each of the three strategies mentioned above.

DiPiro: Pharmacotherapy A Pathophysiologic Approach, 12e

Chapter e21: Pediatrics: Oral Nutrition and Rehydration of Infants and Children

Katherine H. Chessman

KEY CONCEPTS

KEY CONCEPTS

① Human milk is the preferred source of nutrition for almost all neonates and infants, including those born prematurely.

② A commercial infant formula is a nutritionally complete substitute if human milk is not available.

③ Cow milk-based formulas are consumed by most US non-breastfeeding infants, although there is increasing usage of other types of infant formulas.

④ When sufficient maternal or donor milk is not available, specific formulas designed for preterm low birth weight infants can be used to meet nutritional needs.

⑤ Some infants will require specialized formulas with altered macronutrients due to cow milk or soy protein sensitivities or conditions that lead to impaired nutrient digestion, absorption, or utilization.

⑥ Two nutrients, iron and vitamin D, are of particular importance in infant nutrition.

⑦ Human milk contains a variety of non-nutritive compounds with specific bioactive characteristics; formula manufacturers continue to modify their products to include these compounds.

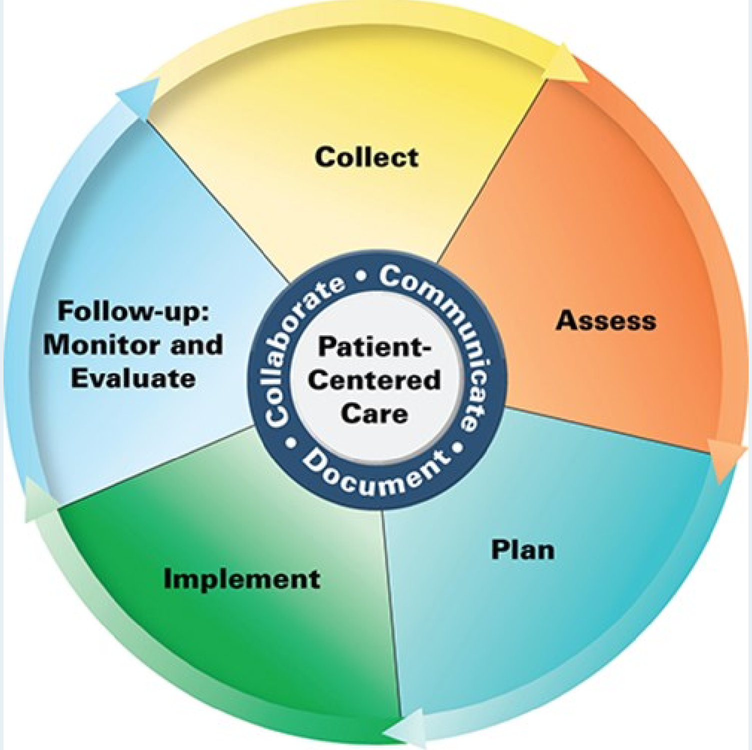
⑧ Enteral formulas are available for children who need supplemental nutrition beyond a regular diet in most of the infant formula categories discussed and are used for similar indications.

⑨ Expressed human milk and infant formulas must be handled and stored properly.

⑩ Oral rehydration therapy (ORT) is a mainstay of treatment for mild-to-moderate dehydration; severe dehydration requires intravenous (IV) rehydration.

PATIENT CARE PROCESS

Patient Care Process* for Oral Nutrition and Rehydration of Infants and Children



Collect
Assess
Plan
Implement
Follow-up: Monitor and Evaluate
Patient-Centered Care
Collaborate • Communicate • Document •

Collect

- Patient characteristics (eg, age, diagnosis)
- Patient history (eg, medical, surgical, dietary)
    - Feeding history: human milk or formula (type, volume, caloric density)
- Objective data
    - Body weight
    - Length/stature, body mass index, head circumference
    - Labs, if appropriate, to assess alterations in organ function (eg, serum electrolytes, glucose, blood urea nitrogen/serum creatinine, albumin, liver function tests)
    - Intake and output (stools, vomiting, urine output)

Assess

- Nutrition status
- Evaluate data for factors that would dictate formula selection
- Determine degree of dehydration and appropriateness of ORT

Plan*

- Choose an appropriate oral/enteral formula based on characteristics of the infant, child, or adolescent (see Chapter 166, “Enteral Nutrition”)
- Recommend an alternative formula, when needed

- Develop a plan to meet an infant's iron and vitamin D needs based on current guidelines
- Make a referral to another provider (eg, physician, dietitian, lactation specialist), when appropriate
- Develop a plan for ORT for a patient with mild-to-moderate dehydration

Implement*

- Provide appropriate oral/enteral support using estimated goals (see Chapter 164, "Assessment of Nutrition Status and Nutrition Requirements")
- Provide an iron or vitamin D supplement to prevent deficiency
- Provide ORT per established guidelines
- Provide patient/caregiver education regarding the nutrition care or ORT plan

Follow-up: Monitor and Evaluate

- Appropriate growth (weight, length, head circumference)
- Gastrointestinal symptoms, tolerance to formula
- Laboratory parameters, as indicated
- Improvement in signs and symptoms of dehydration

* *Collaborate with patient, caregivers, and other healthcare professionals.*

BEYOND THE BOOK

BEYOND THE BOOK

These activities are useful to enhance student understanding of the ASSESS and PLAN steps in the patient care process.

Part #1: For each case, use the manufacturer's websites provided to locate an appropriate infant formula.

Manufacturer	Website
Abbott Nutritionals	abbottnutrition.com
Gerber	medical.gerber.com
Mead Johnson Nutritionals	meadjohnson.com
Nestlé	nestlemedicalhub.com
Nutricia	nutricia-na.com

Case 1: Healthy, term baby whose mother desires to use a standard term infant formula rather than breastfeed.

List one potential option from each of these manufacturers: Abbott, Gerber, Mead Johnson

Case 2: Preterm baby born at 28 weeks gestation, being discharged home today from the NICU. Provider wishes to send the baby home on a preterm transition formula.

List one potential option from each of these manufacturers: Abbott, Mead Johnson

Case 3: A 3-month-old infant with signs and symptoms of cow milk protein allergy is being seen in clinic today. The baby's provider is looking for a hypoallergenic (free amino acid) infant formula.

List one potential option from each of these manufacturers: Abbott, Nestlé, Nutricia

Answers (examples, others may also be appropriate):

Case 1: Abbott: Similac Pro-Advance®; Mead Johnson: Enfamil® NeuroPro™ Infant®; Gerber: Gerber® Good Start® GentlePro

Case 2: Abbott: Similac® Neosure®; Mead Johnson: Enfamil® Enfacare®

Case 3: Abbott: Elecare®; Nestlé: Alfamino® Infant; Nutricia: Neocate® Synveo® Infant

Part #2: Review the patient case descriptions below and match the patient with the most appropriate formula. Each formula choice can be used only once.

Patient Case	Formula
1. Healthy term infant	A. Elecare®
2. Term baby with galactosemia	B. Human milk with HMF (human milk fortifiers)
3. A 6-week-old infant with mild gastroesophageal reflux, starting non-pharmacologic therapy	C. Neocate®
4. Premature baby born at 26 weeks gestational age, now 9 weeks old, weight 2,050 g, being discharged to home	D. Ketocal® 3:1
5. A 4-week-old born with jejunal atresia, diagnosed with short bowel syndrome, beginning low volume feeds	E. Monogen®
6. A 3-year-old with gastrostomy tube needing nutrition supplementation due to growth faltering	F. Similac® Sensitive
7. Premature baby; gestational age 26 weeks, now 2 weeks old, weight 1,190 g	G. Similac® Neosure®
8. An 8-week-old baby who underwent repair of a congenital heart defect and has a chylothorax	H. Similac® Pro-Advance®
9. A 10-month-old baby with intractable seizures starting ketogenic diet	I. Gerber® Good Start® Soy
10. A 4-week-old baby with bloody stools, diagnosed with proctocolitis due to severe cow milk protein allergy	J. Nutren Junior®

Answers:

10. C

INTRODUCTION

Nutrition in the first 1,000 days of life can play a pivotal role in infants, especially those born prematurely. Appropriate early nutrition is essential for growth and development to prevent adverse health outcomes later in life and improve cognition in adulthood. Obesity, hypertension, and diabetes mellitus may be programmed by nutrition status during this period.[1] Infancy is a period of rapid growth which is followed by continued but slower growth and development throughout childhood. Healthy term infants will double their birth weight in approximately 4 months and triple it by 12 months. Adequate nutrient intake, absorption, and utilization are vital to ensuring that growth and development progress normally. All practitioners providing health care for infants and children should be knowledgeable about appropriate pediatric nutrition to be able to quickly identify opportunities for intervention. Dietary reference intakes (DRIs)[2] established by the Food and Nutrition Board of the National Academies of Science, Engineering, and Medicine, for energy, protein, fat, trace elements, vitamins, electrolyte, and mineral requirements are discussed in Chapter 164. There are many choices for both standard and specialized formulas for infants and children. This chapter will review human milk and the various available formulas and their appropriate usage. Adolescents requiring nutrition supplementation beyond a regular diet will typically use feeding formulations appropriate for adults (see Chapter 166). Oral rehydration therapy will also be discussed in this chapter.

INFANT NUTRITION

A term newborn’s stomach has a capacity of 20-90 mL. Gastric capacity increases to 90 to 180 mL by 1 month of age. Too rapidly advancing oral or enteral nutrition intake can lead to emesis, gastroesophageal reflux (GER), and other gastrointestinal (GI) symptoms. Frequent feedings (every 2-3 hours) are needed early in life due to the stomach’s limited capacity and an infant’s high metabolic demand (see Table e21-1). Human milk empties from the stomach at a faster rate than formula; thus, breastfed infants fed ad libitum (ad lib) may demand feeding more often than their formula-fed peers. Nutritive sucking ability develops at approximately 34 weeks gestational age; before that time, tube feedings are required. The inability to coordinate sucking, swallowing, and breathing when the respiratory rate is elevated above 60 breaths per minute also may necessitate tube feeding.

TABLE e21-1

Frequency and Volume of Feedings in Infants

Age	Daily Feedings	Volume per Feeding mL (ounces)
Birth-1 week	6-10	30- 90 (1-3)
1 week-1 month	7- 8	60-120 (2-4)
1-3 months	5-7	120-180 (3-6)
3-6 months	4-5	180-210 (6-7)
6-9 months	3-4	210-240 (7-8)
9-12 months	3	210- 240 (7-8)

Human Milk

① Human milk is the preferred source of nutrition for almost all neonates and infants, including those born prematurely. However, human milk does not fully meet the nutritional needs of all premature infants, and fortification is often required. The American Academy of Pediatrics (AAP)[3], the World Health Organization (WHO)[4], and the Academy of Breastfeeding Medicine (ABM)[5] recommend exclusive breastfeeding (or use of human milk if tube- or bottle-fed) for 6 months, and the use of iron-fortified formula when human milk is not available. After 6 months, complementary foods can be introduced; however, continued breastfeeding or provision of expressed human milk or iron-fortified formula is recommended until the infant is 12[3] to 24[4,5] months of age or for as long as desired.

Of infants born in 2017, 84.1% started breastfeeding at birth with 58.3% breastfeeding at 6 months, a rate only slightly higher than the 2015 rate. Despite the AAP/WHO/ABM recommendations for exclusive breastfeeding until 6 months, only 47% of infants were exclusively breastfed at 3 months, and this percentage dropped to 26% by 6 months. By 12 months of age, only 35% were still breastfeeding to some degree. While the 6-month breastfeeding rate was higher, the 12-month rate was slightly lower than for infants born in 2015.[6] The high breastfeeding initiation rate reflects an increasing desire by US mothers to breastfeed their infants, and the stronger emphasis placed on breastfeeding by the US hospitals through the WHO Baby-Friendly Hospital Initiative (BFHI) which began in 1991. The BFHI assists hospitals in giving mothers the information, confidence, and skills to successfully initiate and continue breastfeeding and gives special recognition to hospitals that have implemented the program. More than 20,000 maternity facilities in 150 countries (600 facilities in the United States) have earned the Baby-Friendly Hospital designation.[7]

The health benefits of breastfeeding for both the baby and the mother are numerous (see Table e21-2). Human milk is well tolerated, promotes the development of immune function, and is associated with less diarrhea and other common pediatric infections. Protective antibodies, including SARS-CoV-2 antibodies, are transmitted to infants in human milk.[8] Human milk feeding has been associated with life-long benefits such as higher intelligent quotients (IQ) scores[9] and decreased risk of obesity[10,11] and type 1 and 2 diabetes mellitus.[12] It is less clear whether the use of human milk protects against atopic dermatitis and other allergies.[13] In addition to health and nutrition benefits, breastfeeding is less expensive, more convenient, and promotes mother-child bonding.

TABLE e21-2

Benefits of Human Milk/Breastfeeding

Benefits to Infant	Benefits to Mother	Benefits to Society
Complete nutrition[a]	Improved mother-child bonding	Improved mother-child bonding
Demonstrated growth and development benefits	Decreased postpartum bleeding	Decreased cost of supplemental formula through WIC program
Improved mother-child bonding	Decreased time to uterus involution	Decreased lost time from work due to infant illnesses
Decreased rates of upper respiratory tract infections (RSV, otitis media), GI disease (diarrhea, NEC, IBD), asthma, atopic dermatitis, obesity, type 1 and type 2 DM, hypertension, childhood leukemia, SUID	Decreased rates of postpartum depression, type 2 DM, hypertension, cardiovascular disease, rheumatoid arthritis, breast and ovarian cancer	Decreased overall healthcare costs, decreased disease burden
Higher IQ scores	Faster return to pre-pregnancy weight	
	Decreased cost	

[a] Vitamin D is required for all; iron is required in some.

DM, diabetes mellitus; GI, gastrointestinal; IBD, inflammatory bowel disease; IQ, intelligence quotient; NEC, necrotizing enterocolitis; RSV, respiratory syncytial virus; SUID, sudden unexpected infant death; WIC, Supplemental Nutrition Program for Women, Infants, and Children.

There are few disadvantages or contraindications to human milk feeding. Breastfed infants may develop unconjugated hyperbilirubinemia (*breast milk jaundice* or *suboptimal intake jaundice of the newborn*), but this rarely necessitates breastfeeding discontinuation.[14] Occasionally, a mother may have to alter dietary intake to alleviate symptoms (gas, GER) in the infant. Breastfeeding or the use of mother's milk is contraindicated in mothers receiving chemotherapy and certain other medications such as amphetamines, ergotamine, and statins; mothers who are taking phencyclidine, cocaine, or cannabis; mothers with active brucellosis; and, in infants with galactosemia who require a lactose-free diet. While caution should be used, mothers enrolled in methadone clinics or who consume less than 0.5 g/kg alcohol right after nursing can breastfeed.[15] One comprehensive resource for information related to the use of drugs in lactation and breastfeeding is LactMed (https://toxnet.nlm.nih.gov/newtoxnet/lactmed.htm).
